## General Topology

### 1.1 Equivalent axiomatizations

In the first lecture of Topology, we learned that a topological space  $(X, \tau)$  is a space  $X$  with a topology  $\tau \subseteq \mathcal{P}(X)$  such that  $\tau$  satisfy the following three axioms.

$$\begin{cases} X, \emptyset \in \tau \\ \forall O, Y \in \tau, O \cap Y \in \tau \text{ (Closed under finite intersection)} \\ \forall T \subseteq \mathcal{P}(\tau), \bigcup T \in \tau \text{ (Closed under arbitrary union)} \end{cases} \quad (1.1)$$

It is only after the explicit listing of the above three of open sets, we then start defining "closed sets", "neighborhoods", "continuous functions", "compact sets" or "connected sets" based on open sets.

Although this approach, axiomatization via open sets, is mathematically sufficient, in history, there are other axiomatization proved to be equivalent to the traditional axiomatization via open sets.

In this section, we will give other three axiomatizations of topology, via neighborhood systems, via nets and via filters, and show they are equivalent with each other.

In this note, a *neighborhood system* is a function  $\mathcal{N} : X \rightarrow \mathcal{P}(\mathcal{P}(X))$ . We shall first show that there exists an explicit one-to-one correspondence between collection of topologies on  $X$  and collection of neighborhood systems that satisfy the following axioms.

**Axiom 1.1.1. (Axioms of neighborhood systems)**

$$\left\{ \begin{array}{l} \forall x \in X, \mathcal{N}(x) \neq \emptyset \text{ (Non empty)} \\ \forall x \in X, \forall M \in \mathcal{N}(x), x \in M \text{ (Around)} \\ \forall x \in X, \forall M \subseteq X, \exists N \in \mathcal{N}(x), N \subseteq M \implies M \in \mathcal{N}(x) \text{ (Closed under superset)} \\ \forall x \in X, \forall M, N \in \mathcal{N}(x), M \cap N \in \mathcal{N}(x) \text{ (Closed under finite intersection)} \\ \forall x \in X, \forall M \in \mathcal{N}(x), \exists N \in \mathcal{N}(x), N \subseteq M \text{ and } \forall y \in N, M \in \mathcal{N}(y) \text{ (Open neighborhood)} \end{array} \right.$$

Suppose  $C$  is the collection of topologies on  $X$  and  $D$  is the collection of neighborhood systems that satisfy Axioms 1.1.1. Now we wish to prove that the function  $f : C \rightarrow D$

$$\tau \mapsto \mathcal{N}_\tau \text{ where } \mathcal{N}_\tau(x) = \{A \in \mathcal{P}(X) : \exists O \in \tau, x \in O \subseteq A\} \quad (1.2)$$

is bijective. In order to prove this, we first have to prove that  $f$  is well-defined, meaning for each topology  $\tau$ , the function  $\mathcal{N}_\tau$  is indeed a neighborhood system that satisfy the above axioms. This is easy, which we will omit here. It remains that we have to prove two statements:  $f$  is one-to-one, and  $f$  is onto.

**Theorem 1.1.2. ( $f$  in Equation 1.2 is one-to-one)** As titled.

*Proof.* Suppose  $\tau$  and  $\tau'$  are two different topologies on  $X$ . WOLG, suppose  $O \in \tau \setminus \tau'$ . By definition of  $f$  (Equation 1.2), we know

$$\forall x \in O, O \in \mathcal{N}_\tau(x)$$

This means, to prove  $\mathcal{N}_\tau \neq \mathcal{N}_{\tau'}$ , we only have to prove the existence of some  $x \in O$  such that  $O \notin \mathcal{N}_{\tau'}(x)$ . Assume  $\forall x \in O, O \in \mathcal{N}_{\tau'}(x)$ . By definition of  $f$  (Equation 1.2), we can deduce  $\forall x \in O, \exists A_x \in \tau', x \in A_x \subseteq O$ . It is easy to verify that  $O = \bigcup_{x \in O} A_x$ . Then by Axiom 1.1 of open sets, we  $O = \bigcup_{x \in O} A_x \in \tau'$  **CaC** to that  $O \in \tau \setminus \tau'$ . ■

To prove  $f$  is onto is a little bit complicated.

**Theorem 1.1.3. ( $f$  in Equation 1.2 is onto)** As titled.

*Proof.* Define  $g : D \rightarrow C$  by

$$\mathcal{N} \mapsto \sigma_{\mathcal{N}} \text{ where } \sigma_{\mathcal{N}} = \{O \in \mathcal{P}(X) : \forall x \in O, O \in \mathcal{N}(x)\} \quad (1.3)$$

It is easy to check for each neighborhood system  $\mathcal{N} : X \rightarrow \mathcal{P}(\mathcal{P}(X))$  satisfying Axioms 1.1.1, the collection  $\sigma_{\mathcal{N}}$  is a topology.

Then, to prove  $f$  is onto, it suffice to prove

$$\forall \mathcal{N} \in D, \mathcal{N} = f(\sigma_{\mathcal{N}})$$

In other words, we wish to prove

$$\forall \mathcal{N} \in D, \forall x \in X, \mathcal{N}(x) = (f(\sigma_{\mathcal{N}}))(x)$$

By definition of  $f$  (Equation 1.2), we know

$$(f(\sigma_{\mathcal{N}}))(x) = \{A \in \mathcal{P}(X) : \exists O \in \sigma_{\mathcal{N}}, x \in O \subseteq A\} \quad (1.4)$$

Suppose  $A \in (f(\sigma_{\mathcal{N}}))(x)$ . Let  $O \in \sigma_{\mathcal{N}}$  satisfy  $x \in O \subseteq A$ . By definition of  $g$  (Equation 1.3), we know  $O \in \mathcal{N}(x)$ . Then because Axiom 1.1.1 says that  $\mathcal{N}(x)$  is closed under superset, we now see  $A \in \mathcal{N}(x)$ . We have proved  $(f(\sigma_{\mathcal{N}}))(x) \subseteq \mathcal{N}(x)$ .

Suppose  $M \in \mathcal{N}(x)$ . By the fifth axiom listed in Axiom 1.1.1, we know there exists some  $N \in \mathcal{N}(x)$  such that  $N \subseteq M$  and  $\forall y \in N, M \in \mathcal{N}(y)$ . Notice that the union of such  $N$  is still a subset of  $M$  and  $M$  is a neighborhood of each point in the union. This means that there exists a maximum  $N$  that satisfy

$$\begin{cases} N \subseteq M \\ \forall y \in N, M \in \mathcal{N}(y) \end{cases}$$

We now prove  $N \in \sigma_{\mathcal{N}}$ . Arbitrarily pick  $z \in N$ , by definition of  $N$  above, we can deduce  $M \in \mathcal{N}(z)$ . Then by the fifth axiom listed in Axiom 1.1.1, we know there exists some  $N' \in \mathcal{N}(z)$  satisfying  $N' \subseteq M$  and  $\forall y \in N', M \in \mathcal{N}(y)$ . Because  $N$  by definition is the maximum of such neighborhood, we see  $N' \subseteq N$ . Then because Axiom 1.1.1 says that  $\mathcal{N}(z)$  is closed under superset, we see  $N \in \mathcal{N}(z)$ .

We have shown  $\forall z \in N, N \in \mathcal{N}(z)$ . Then by definition of  $g$  (Equation 1.3), we see  $N \in \sigma_{\mathcal{N}}$  (done) .

Then because  $N \subseteq M$  by definition of  $N$  and because  $N \in \sigma_{\mathcal{N}}$ , we see  $M \in (f(\sigma_{\mathcal{N}}))(x)$ , according to Equation 1.4. We have proved  $\mathcal{N}(x) \subseteq (f(\sigma_{\mathcal{N}}))(x)$  (done) ■

Before embarking on the axiomatization via nets, we first have to settle the terminologies. Recall that a set  $D$  is **directed** if there exists an ordering  $\leq$  on  $D$  such that  $\leq$  is reflexive, transitive, and we have  $\forall i, j \in D, \exists k \in D, i \leq k$  and  $j \leq k$ . By a **net**, we mean a function  $w$  whose domain is directed. We say a subset  $D'$  of a directed set is **cofinal** if  $\forall d \in D, \exists d' \in D', d \leq d'$ . By a **subnet** of  $w : D \rightarrow X$ , we mean a net

$v : E \rightarrow X$  such that there exists  $h : E \rightarrow D$  such that

$$\begin{cases} \forall e, e' \in E, e \leq e' \implies h(e) \leq h(e') \text{ (Monotone)} \\ h[E] \text{ is cofinal} \\ v = w \circ h \end{cases}$$

One can check that when  $w$  is a sequence  $x_n$  and  $v$  is the sub-sequence  $x_{n_k}$ , the corresponding  $h$  is just  $n_k$ .

By a **tail**  $T_d$  of a directed set  $D$ , we mean  $T_d = \{e \in D : d \leq e\}$ . We say  $w : D \rightarrow X$  **is eventually in**  $A \subseteq X$  if  $\exists d \in D, w[T_d] \subseteq A$ . We say  $w : D \rightarrow X$  **is frequently in**  $A \subseteq X$  if  $\forall d \in D, \exists e \in T_d, w(e) \in A$ . Given a topological space  $(X, \tau)$ , we say  $w$  **converge** to a point  $x$ , if for all neighborhood  $O$  around  $x$  there exists  $d \in D$  such that  $w[T_d] \subseteq O$ . Notice that if we wish to prove  $w \rightarrow x$  we only have to verify for all open neighborhoods  $O$  around  $x$ . Also notice that  $w$  can converge to multiple points. A trivial example is when two point are topologically indistinguishable.

## 2.5 Holder Continuity

## 2.6 Limit Interchange

Given an arbitrary set  $X$  and a complete metric space  $(\bar{Y}, d)$ , in Section 2.8, we have proved that the set of functions with the following properties

- (a) boundedness
- (b) unboundedness

are respectively closed under uniform convergence. In next section (Section 2.7), we will prove that the following three properties

- (a) continuity
- (b) uniform continuity
- (c)  $K$ -Lipschitz continuity

are again all closed under uniform convergence, where the proof for continuity is closed under uniform convergence use Theorem 2.6.1 as a lemma.

Here, we prove

- (a) convergent of sequences

in, of course, complete metric space, is also closed under uniform convergence.

The reason we require the codomain  $\bar{Y}$  of sequence to be complete is explained in the last paragraph of Section 2.8. An example of such beautiful closure is lost if the codomain  $(Y, d)$  is not complete is  $Y = \mathbb{R}^*$  and  $a_{n,k} = \frac{1}{n} + \frac{1}{k}$ .

**Theorem 2.6.1. (Change Order of Limit Operations: Part 1)** Given a double sequence  $a_{n,k}$  whose codomain is  $(Y, d)$ . Suppose

- (a)  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly as  $n \rightarrow \infty$
- (b)  $a_{n,k} \rightarrow A_n$  pointwise as  $k \rightarrow \infty$ .
- (c)  $A_n \rightarrow A$

Then we can deduce

$$\lim_{k \rightarrow \infty} a_{\bullet,k} \text{ exists and } \lim_{k \rightarrow \infty} a_{\bullet,k} = A$$

In other words, we can switch the order of limit operations

$$\lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} a_{n,k} = \lim_{n \rightarrow \infty} \lim_{k \rightarrow \infty} a_{n,k}$$

*Proof.* We wish to prove

$$a_{\bullet,k} \rightarrow A \text{ as } k \rightarrow \infty$$

Fix  $\epsilon$ . Because  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly and  $A_n \rightarrow A$  as  $n \rightarrow \infty$ , we know there exists  $m$  such that

$$d(A_m, A) < \frac{\epsilon}{3} \text{ and } \forall k \in \mathbb{N}, d(a_{m,k}, a_{\bullet,k}) < \frac{\epsilon}{3} \quad (2.1)$$

Then because  $a_{m,k} \rightarrow A_m$  as  $k \rightarrow \infty$ , we know there exists  $K$  such that

$$\forall k > K, d(a_{m,k}, A_m) < \frac{\epsilon}{3} \quad (2.2)$$

We now claim

$$\forall k > K, d(a_{\bullet,k}, A) < \epsilon$$

The claim is true since by Equation 2.1 and Equation 2.2, we have

$$\forall k > K, d(a_{\bullet,k}, A) \leq d(a_{\bullet,k}, a_{m,k}) + d(a_{m,k}, A_m) + d(A_m, A) < \epsilon \text{ (done)}$$

■

**Theorem 2.6.2. (Change Order of Limit Operations: Part 2)** Given a double sequence  $a_{n,k}$  whose codomain is  $(Y, d)$ . Suppose

- (a)  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly as  $n \rightarrow \infty$
- (b)  $a_{n,k} \rightarrow A_n$  pointwise as  $k \rightarrow \infty$
- (c)  $a_{\bullet,k} \rightarrow A$  as  $k \rightarrow \infty$

Then we can deduce

$$A_n \text{ converge and } A_n \rightarrow A$$

*Proof.* Fix  $\epsilon$ . We wish to find  $N$  such that

$$\forall n > N, d(A_n, A) < \epsilon$$

Because  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly as  $n \rightarrow \infty$ , we can let  $N$  satisfy

$$\forall n > N, \forall k \in \mathbb{N}, d(a_{n,k}, a_{\bullet,k}) < \frac{\epsilon}{3} \quad (2.3)$$

We claim

$$\text{such } N \text{ works}$$

Arbitrarily pick  $n > N$ . Because  $a_{\bullet,k} \rightarrow A$ , and because  $a_{n,k} \rightarrow A_n$ , we know there exists  $j$  such that

$$d(a_{\bullet,j}, A) < \frac{\epsilon}{3} \text{ and } d(a_{n,j}, A_n) < \frac{\epsilon}{3} \quad (2.4)$$

From Equation 2.3 and Equation 2.4, we now have

$$d(A_n, A) \leq d(A_n, a_{n,j}) + d(a_{n,j}, a_{\bullet,j}) + d(a_{\bullet,j}, A) < \epsilon \text{ (done)}$$

■

**Corollary 2.6.3. (Change Order of Limit Operation in Complete Metric Space)**

Given a sequence of function  $f_n : E \rightarrow (Y, d)$  and a function  $f : E \rightarrow (Y, d)$  such that

- (a)  $f_n$  converge uniformly
- (b)  $\lim_{t \rightarrow x} f_n(t)$  exists for all  $n \in \mathbb{N}$
- (c)  $(Y, d)$  is complete

We have

$$\lim_{n \rightarrow \infty} \lim_{t \rightarrow x} f_n(t) = \lim_{t \rightarrow x} \lim_{n \rightarrow \infty} f_n(t)$$

*Proof.* Fix a sequence  $t_k$  in  $E$  that converge to  $x$ . We reduced the problem into proving

$$\lim_{n \rightarrow \infty} \lim_{k \rightarrow \infty} f_n(t_k) = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} f_n(t_k)$$

Set

$$a_{n,k} \triangleq f_n(t_k) \quad (2.5)$$

We then reduced the problem into proving

$$\lim_{n \rightarrow \infty} \lim_{k \rightarrow \infty} a_{n,k} = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} a_{n,k}$$

Set

$$A_n \triangleq \lim_{t \rightarrow x} f_n(t) \text{ and } a_{\bullet,k} \triangleq \lim_{n \rightarrow \infty} f_n(t_k)$$

We now prove

$A_n$  converge

Fix  $\epsilon$ . We wish

to find  $N$  such that  $d(A_n, A_m) \leq \epsilon$  for all  $n, m > N$

Because  $a_{n,k}$  uniformly converge (to  $a_{\bullet,k}$ ) as  $n \rightarrow \infty$  by our setting, we know there exists  $N$  such that

$$\forall n, m > N, \forall k \in \mathbb{N}, d(a_{n,k}, a_{m,k}) < \frac{\epsilon}{3}$$

We claim

such  $N$  works

Fix  $n, m > N$ . Because  $a_{n,k} \rightarrow A_n$  and  $a_{m,k} \rightarrow A_m$ , we know there exists  $j \in \mathbb{N}$  such that

$$d(a_{n,j}, A_n) < \frac{\epsilon}{3} \text{ and } d(a_{m,j}, A_m) < \frac{\epsilon}{3}$$

We now have

$$\begin{aligned} d(A_n, A_m) &\leq d(A_n, a_{n,j}) + d(a_{n,j}, a_{m,j}) + d(a_{m,j}, A_m) \\ &< \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon \text{ (done)} \end{aligned}$$

Now, because  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly, by Theorem 2.6.2, we have

$$\lim_{n \rightarrow \infty} \lim_{k \rightarrow \infty} a_{n,k} = \lim_{n \rightarrow \infty} A_n = \lim_{k \rightarrow \infty} a_{\bullet,k} = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} a_{n,k} \text{ (done)}$$

■

In summary of Theorem 2.6.1 and Theorem 2.6.2, given a double sequence  $a_{n,k}$  converging both side

- (a)  $a_{n,k} \rightarrow a_{\bullet,k}$  pointwise as  $n \rightarrow \infty$
- (b)  $a_{n,k} \rightarrow a_{n,\bullet}$  pointwise as  $k \rightarrow \infty$

As long as

- (a) one side of convergence is uniform
- (b) between two sequence  $\{a_{\bullet,k}\}_{k \in \mathbb{N}}$  and  $\{a_{n,\bullet}\}_{n \in \mathbb{N}}$ , one of them converge, say, to  $A$

Then the other sequence also converge, and the limit is also  $A$ .

It is at this point, we shall introduce two other terminologies. Suppose  $f_n$  is a sequence of functions from an arbitrary set  $X$  to a metric space  $Y$ . We say  $f_n$  is **pointwise Cauchy** if for all fixed  $x \in X$ , the sequence  $f_n(x)$  is Cauchy. We say  $f_n$  is **uniformly Cauchy** if for all  $\epsilon$ , there exists  $N \in \mathbb{N}$  such that

$$\forall n, m > N, \forall x \in X, d(f_n(x), f_m(x)) < \epsilon$$

In last Section (Section 2.8), we define the **uniform metric**  $d_\infty$  on  $X^Y$  by

$$d_\infty(f, g) = \sup_{x \in X} d(f(x), g(x))$$

and say that  $f_n \rightarrow f$  uniformly if and only if  $f_n \rightarrow f$  in  $(X^Y, d_\infty)$ . Similar to this clear fact, we have

$$f_n \text{ is uniformly Cauchy} \iff f_n \text{ is Cauchy in } (X^Y, d_\infty)$$

It should be very easy to verify that if  $f_n$  uniformly converge, then  $f_n$  is uniformly Cauchy, and just like sequences in metric space, the converse hold true if and only if the space  $(X^Y, d_\infty)$  is complete. In Theorem 2.6.4, we give a necessary and sufficient condition for  $(X^Y, d_\infty)$  to be complete.

**Theorem 2.6.4. (Space of functions  $(X^Y, d_\infty)$  is Complete iff  $Y$  is Complete)**

Given an arbitrary set  $X$  and a metric space  $(Y, d)$ , we have

$$\text{the extended metric space } (X^Y, d_\infty) \text{ is complete} \iff Y \text{ is complete}$$

*Proof.* ( $\longleftarrow$ )

Suppose  $f_n$  is uniformly Cauchy. We wish

to construct a  $f : X \rightarrow Y$  such that  $f_n \rightarrow f$  uniformly

Because  $f_n$  is uniformly Cauchy, we know that for all  $x \in X$ , the sequence  $f_n(x)$  is Cauchy in  $(Y, d)$ . Then because  $Y$  is complete, we can define  $f : X \rightarrow Y$  by

$$f(x) = \lim_{n \rightarrow \infty} f_n(x)$$

We claim

such  $f$  works, i.e.  $f_n \rightarrow f$  uniformly

Fix  $\epsilon$ . We wish

to find  $N \in \mathbb{N}$  such that for all  $n > N$  and  $x \in X$  we have  $d(f_n(x), f(x)) < \epsilon$

Because  $f_n$  is uniformly Cauchy, we know there exists  $N$  such that

$$\forall n, m > N, \forall x \in X, d(f_n(x), f_m(x)) < \frac{\epsilon}{2} \tag{2.6}$$

We claim

such  $N$  works

Assume **there exists**  $n > N$  and  $x \in X$  such that  $d(f_n(x), f(x)) \geq \epsilon$ . Because  $f_k(x) \rightarrow f(x)$  as  $k \rightarrow \infty$ , we know

$$\exists m \in \mathbb{N}, d(f_m(x), f(x)) < \frac{\epsilon}{2} \quad (2.7)$$

Then from Equation 2.6 and Equation 2.7, we can deduce

$$\epsilon \leq d(f_n(x), f(x)) \leq d(f(x), f_m(x)) + d(f_n(x), f_m(x)) < \epsilon \text{ CaC (done)}$$

( $\longrightarrow$ )

Let  $K$  be the set of constant functions in  $X^Y$ . We first prove

$K$  is closed

Arbitrarily pick  $f \in K^c$ . We wish

to find  $\epsilon \in \mathbb{R}^+$  such that  $B_\epsilon(f) \in K^c$

Because  $f$  is not a constant function, we know there exists  $x_1, x_2 \in X$  such that

$$d(f(x_1), f(x_2)) > 0$$

We claim that

$$\epsilon = \frac{d(f(x_1), f(x_2))}{3} \text{ works}$$

Arbitrarily pick  $g \in B_\epsilon(f)$ . We wish

to show  $g \in K^c$

Notice the triangle inequality

$$3\epsilon = d(f(x_1), f(x_2)) \leq d(f(x_1), g(x_1)) + d(g(x_1), g(x_2)) + d(g(x_2), f(x_2)) \quad (2.8)$$

Also, because  $g \in B_\epsilon(f)$ , we have

$$\forall x \in X, d(f(x), g(x)) < \epsilon \quad (2.9)$$

Then by Equation 2.8 and Equation 2.9, we see

$$d(g(x_1), g(x_2)) > \epsilon$$

This then implies  $g$  is not a constant function. (done)

Now, Because by premise  $(X^Y, d_\infty)$  is complete, and we have proved  $K$  is closed in  $(X^Y, d_\infty)$ , we know  $K$  is complete. Then, we resolve the whole problem into proving

$Y$  is isometric to  $K$

Define  $\sigma : Y \rightarrow K$  by

$$y \mapsto \tilde{y} \text{ where } \forall x \in X, \tilde{y}(x) = y$$

It is easy to verify  $\sigma$  is an isometry. (done) ■

**Corollary 2.6.5. (Space of Bounded functions  $(B(X, Y), d_\infty)$  is Complete iff  $Y$  is Complete)**

$$(B(X, Y), d_\infty) \text{ is complete} \iff Y \text{ is complete}$$

*Proof.* ( $\longleftarrow$ )

By Theorem 2.6.4, the space  $(X^Y, d_\infty)$  is complete. Then because  $B(X, Y)$  is closed in  $(X^Y, d_\infty)$ , we know  $B(X, Y)$  is complete.

( $\longrightarrow$ )

Notice that the set of constant function  $K$  is a subset of the galaxy  $B(X, Y)$ . The whole proof in Theorem 2.6.4 works in here too. ■

Remember in the beginning of this section we say we will prove convergent sequences in  $Y$  is closed under uniform convergence if  $Y$  is complete. The proof of this result relies on Theorem 2.6.4.

Now, before we actually prove convergence sequences are closed under uniform convergence if codomain  $(Y, d)$  is complete (Theorem 2.6.7), we will state and prove Weierstrass M-test (Theorem 2.6.6), which concerns the uniform convergence of series of complex functions.

**Theorem 2.6.6. (Weierstrass M-test)** Given sequences  $f_n : X \rightarrow \mathbb{C}$ , and suppose

$$\forall n \in \mathbb{N}, \forall x \in X, |f_n(x)| \leq M_n \tag{2.10}$$

Then

$$\sum_{n=1}^{\infty} M_n \text{ converge} \implies \sum_{n=1}^{\infty} f_n \text{ uniformly converge}$$

*Proof.* Because  $(\mathbb{C}, \|\cdot\|_2)$  is complete, by Corollary 2.6.5, we only wish to prove

$$\left\{ \sum_{k=1}^n f_k \right\}_{n \in \mathbb{N}} \text{ is uniformly Cauchy}$$

Fix  $\epsilon$ . We wish

$$\text{to find } N \text{ such that } \forall n, m > N, \forall x \in X, \left| \sum_{k=n}^m f_k(x) \right| < \epsilon$$

Because  $\sum_{n=1}^{\infty} M_n$  converge, we know there exists  $N$  such that

$$\forall n, m > N, \sum_{k=n}^m M_k < \epsilon$$

We claim

such  $N$  works

By Premise 2.10, we have

$$\forall n, m > N, \forall x \in X, \left| \sum_{k=n}^m f_k(x) \right| \leq \sum_{k=n}^m |f_k(x)| \leq \sum_{k=n}^m M_k < \epsilon$$

■

**Theorem 2.6.7. (Convergent Sequences are Closed under Uniform Convergence if Codomain  $(Y, d)$  is Complete)** Given a complete metric space  $(Y, d)$ , let  $\mathcal{C}_{\mathbb{N}}^Y$  be the set of convergent sequences in  $Y$ .

$$Y \text{ is complete} \implies \mathcal{C}_{\mathbb{N}}^Y \text{ is closed under uniform convergent}$$

*Proof.* Let  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly as  $n \rightarrow \infty$  where for all  $n, k \in \mathbb{N}, a_{n,k} \in Y$  and let  $A_n = \lim_{k \rightarrow \infty} a_{n,k}$  for all  $n \in \mathbb{N}$ .

to prove  $a_{\bullet,k}$  converge

By Theorem 2.6.2, we can reduce the problem to

proving  $A_n$  converge

Then because  $Y$  is complete, we can then reduce the problem into proving

$A_n$  is Cauchy

Fix  $\epsilon$ . We wish to find  $N$  such that

$$\forall n, m > N, d(A_n, A_m) < \epsilon$$

Because  $a_{n,k} \rightarrow a_{\bullet,k}$  uniformly, we can find  $N$  such that

$$\forall n, m > N, d_\infty(\{a_{n,k}\}_{k \in \mathbb{N}}, \{a_{m,k}\}_{k \in \mathbb{N}}) < \frac{\epsilon}{3} \quad (2.11)$$

We claim

such  $N$  works

Arbitrarily pick  $n, m > N$ . We wish to prove

$$d(A_n, A_m) < \epsilon$$

Because  $a_{n,k} \rightarrow A_n$  and  $a_{m,k} \rightarrow A_m$  as  $k \rightarrow \infty$ , we can find  $j$  such that

$$d(a_{n,j}, A_n) < \frac{\epsilon}{3} \text{ and } d(a_{m,j}, A_m) < \frac{\epsilon}{3} \quad (2.12)$$

Then from Equation 2.11 and Equation 2.12, we can deduce

$$d(A_n, A_m) \leq d(A_n, a_{n,j}) + d(a_{n,j}, a_{m,j}) + d(a_{m,j}, A_m) < \epsilon \text{ (done)}$$

■

## 2.7 Closed under Uniform Convergence

The end goal for this section is to prove that the following properties

- (a) continuity
- (b) uniform continuity
- (c)  $K$ -Lipschitz Continuity

**Theorem 2.7.1. (Uniform Limit Theorem)** Given a sequence of function  $f_n$  from a topological space  $(X, \tau)$  to a metric space  $(Y, d)$ , suppose

- (a)  $f_n \rightarrow f$  uniformly as  $n \rightarrow \infty$
- (b)  $f_n$  is continuous for all  $n \in \mathbb{N}$

Then  $f$  is also continuous.

*Proof.* Fix  $x \in X$ , and let  $x_k \rightarrow x$ . We wish to prove

$$f(x_k) \rightarrow f(x)$$

Because  $f_n \rightarrow f$  uniformly as  $n \rightarrow \infty$ , we know

$$\left\{ f_n(x_k) \right\}_{k \in \mathbb{N}} \rightarrow \left\{ f(x_k) \right\}_{k \in \mathbb{N}} \text{ uniformly as } n \rightarrow \infty \quad (2.13)$$

Also, because for each  $n \in \mathbb{N}$ , the function  $f_n$  is continuous at  $x$ , we know

$$\forall n \in \mathbb{N}, f_n(x_k) \rightarrow f_n(x) \text{ as } k \rightarrow \infty \quad (2.14)$$

Then because  $f_n \rightarrow f$  pointwise, we know

$$f_n(x) \rightarrow f(x) \quad (2.15)$$

Now, because Equation 2.13, Equation 2.14 and Equation 2.15, by Theorem 2.6.1, we have

$$\lim_{k \rightarrow \infty} f(x_k) = \lim_{k \rightarrow \infty} \lim_{n \rightarrow \infty} f_n(x_k) = \lim_{n \rightarrow \infty} \lim_{k \rightarrow \infty} f_n(x_k) = \lim_{n \rightarrow \infty} f_n(x) = f(x) \text{ (done)}$$

■

Suppose  $X$  is a compact Hausdorff space, with Theorem ??, we can now say that the set  $\mathcal{C}(X)$  of complex-valued continuous functions on  $X$

**Theorem 2.7.2. (Uniformly Continuous functions are Closed under Uniform Convergence)** Given a sequence of functions  $f_n$  from a metric space  $(X, d_X)$  to metric space  $(Y, d_Y)$ , suppose

(a)  $f_n \rightarrow f$  uniformly

(b)  $f_n$  is uniformly continuous for all  $n \in \mathbb{N}$

Then  $f$  is also uniformly continuous

*Proof.* Fix  $\epsilon$ . We wish

to find  $\delta$  such that  $\forall x, y \in X, d_X(x, y) < \delta \implies d_Y(f(x), f(y)) < \epsilon$

Because  $f_n \rightarrow f$  uniformly, we know there exists  $m \in \mathbb{N}$  such that

$$\forall x \in X, d_Y(f_m(x), f(x)) < \frac{\epsilon}{3} \quad (2.16)$$

Because  $f_m$  is uniformly continuous, we know

$$\exists \delta, \forall x, y \in X, d_X(x, y) < \delta \implies d_Y(f_m(x), f_m(y)) < \frac{\epsilon}{3} \quad (2.17)$$

We claim

such  $\delta$  works

Let  $x, y \in X$  satisfy  $d_X(x, y) < \delta$ . We wish

to prove  $d_Y(f(x), f(y)) < \epsilon$

From Equation 2.16 and Equation 2.17, we have

$$d_Y(f(x), f(y)) \leq d_Y(f(x), f_m(x)) + d_Y(f_m(x), f_m(y)) + d_Y(f_m(y), f(y)) = \epsilon \text{ (done)}$$

■

**Theorem 2.7.3. ( $K$ -Lipschitz functions are Closed under Uniform Convergence)**

Given a sequence of functions  $f_n$  from metric space  $(X, d_X)$  to metric space  $(Y, d_Y)$ , suppose

(a)  $f_n \rightarrow f$  uniformly as  $n \rightarrow \infty$

(b)  $f_n$  is  $K$ -Lipschitz continuous for all  $n \in \mathbb{N}$

Then  $f$  is also  $K$ -Lipschitz continuous.

*Proof.* Arbitrarily pick  $x, y \in X$ , to show  $f$  is  $K$ -Lipschitz continuous, we wish

to show  $d_Y(f(x), f(y)) \leq K d_X(x, y)$

Fix  $\epsilon$ . We reduce the problem into proving

$$d_Y(f(x), f(y)) < K d_X(x, y) + \epsilon$$

Because  $f_n \rightarrow f$  uniformly as  $n \rightarrow \infty$ , we know there exists  $m$  such that

$$\forall z \in X, d_Y(f(z), f_m(z)) < \frac{\epsilon}{2} \quad (2.18)$$

Because  $f_m$  is  $K$ -Lipschitz continuous, we know

$$d_Y(f_m(x), f_m(y)) \leq K d_X(x, y) \quad (2.19)$$

Now, from Equation 2.19 and Equation 2.18, we now see

$$d_Y(f(x), f(y)) \leq d_Y(f(x), f_m(x)) + d_Y(f_m(x), f_m(y)) + d_Y(f_m(y), f(y)) < K d_X(x, y) + \epsilon$$

■

An example of sequences of Lipschitz continuous functions with unbounded Lipschitz constant can uniformly converge to a non-Lipschitz continuous function is given below

**Example 1 (Lipschitz functions with Unbounded Lipschitz constant Uniformly Converge to a non-Lipschitz function)**

$$X = [0, 1] \text{ and } f_n(x) = \sqrt{x + \frac{1}{n}}$$

## 2.8 Modes of Convergence

This section is the starting point for us to study spaces of function. At first, we will define two modes of convergence for sequence of function and point out some basic properties and the difference between two modes of convergence.

Given an arbitrary set  $X$  and a metric space  $Y$ , we say a sequence of functions  $f_n$  from  $X$  to  $Y$  **pointwise converge** to  $f$  if for all  $\epsilon$  and  $x$  in  $X$ , there exists  $N$  such that

$$\forall n > N, f_n(x) \in B_\epsilon(f(x))$$

In other words, for each fixed  $x$  in  $X$ , we have  $f_n(x) \rightarrow f(x)$ .

We say  $f_n$  **uniformly converge** to  $f$  if for all  $\epsilon$  there exists  $N$  such that

$$\forall x \in X, \forall n > N, f_n(x) \in B_\epsilon(f(x))$$

The difference between pointwise convergence and uniform convergence is that if we require  $f_n(x)$  to be  $\epsilon$ -close to  $f(x)$  for all  $n > N$ , then

- (•)  $N$  depend on both  $\epsilon$  and  $x$  if  $f_n \rightarrow f$  pointwise
- (•)  $N$  depend on only  $\epsilon$  if  $f_n \rightarrow f$  uniformly

A few properties of sequence of functions similar to that of sequences in metric space is obvious. If  $f_n \rightarrow f$  pointwise, then all sub-sequences  $f_{n_k} \rightarrow f$  pointwise. If  $f_n \rightarrow f$  uniformly, then all sub-sequences  $f_{n_k} \rightarrow f$  uniformly. Suppose  $Z \subseteq X$ . It is clear that if  $f_n \rightarrow f$  uniformly (resp: pointwise) the restricts  $f_n|_Z \rightarrow f|_Z$  uniformly (resp: pointwise). Also, if  $f_n \rightarrow f$  uniformly, then  $f_n \rightarrow f$  pointwise.

Suppose we have a family  $\mathcal{F}$  of functions  $f : X \rightarrow (Y, d)$ . If we define

$$d_\infty(f, g) = \sup_{x \in X} d(f(x), g(x))$$

instead of a metric,  $d_\infty$  become an extended metric. If  $f$  is bounded and  $g$  is unbounded, we have  $d_\infty(f, g) = \infty$ . If  $f, g$  are both bounded, then  $d_\infty(f, g) \in \mathbb{R}^+$ . Because of such, for  $d_\infty$  to be a metric, one but not the only condition is for  $\mathcal{F}$  to be space of bounded functions.

Now, regardless of  $d_\infty$  is an extended metric or not, we have

$$f_n \rightarrow f \text{ uniformly} \iff d_\infty(f_n, f) \rightarrow 0$$

With this in mind, it shall be clear that the uniform limit of bounded (resp: unbounded) functions is always bounded (resp: unbounded).

Examples for bounded (resp: unbounded) function  $f_n$  pointwise converge to unbounded (resp: bounded) function  $f$  are as follows.

**Example 2 (Bounded functions pointwise converge to unbounded function)**

$$X = (0, 1], f_n(x) = \min\left\{n, \frac{1}{x}\right\}$$

It is clear that  $\forall n \in \mathbb{N}, f_n(x) \in [0, n]$ , and the limit  $f : X \rightarrow \mathbb{R}$  is  $f(x) = \frac{1}{x}$

**Example 3 (Unbounded functions pointwise converge to bounded function)**

$$X = \mathbb{R}, f_n(x) = \frac{1}{n}x$$

The limit function is  $f(x) = 0$

As pointed out earlier, if  $f : X \rightarrow (Y, d)$  is bounded and  $g : X \rightarrow (Y, d)$  is unbounded, then  $d_\infty(f, g) = \infty$ . This means that if  $Y$  is unbounded, the uniform metric  $d_\infty$  is extended on  $X^Y$ . For this, it is necessary to develop some basic fact concerning extended metric space.

Suppose  $(X, d)$  is an extended metric space. If we define  $\sim$  on  $X$  by  $x \sim y \iff d(x, y) < \infty$ , then  $\sim$  is an equivalence relation. We say each equivalence class is a **galaxy** of  $(X, d)$ . Suppose  $T$  is the collection of the galaxies of  $(X, d)$ . For each  $\mathcal{T} \in T$ , the space  $(\mathcal{T}, d)$  is just a metric space.

It is easy to see that the way we induce topology from metric space is still valid if the metric is extended. That is

$$\tau = \{Z \in X : \forall z \in Z, \exists \epsilon, B_\epsilon(z) \subseteq Z\}$$

is still a topology, even though  $d$  is an extended metric on  $X$ .

We can verify that a set  $Y$  in  $X$  is open if and only if for all  $\mathcal{T} \in T$ , the set  $Y \cap \mathcal{T}$  is open, and the set  $Y$  in  $X$  is closed if and only if all convergent sequences  $y_n$  in  $Y$

converge to points in  $Y$ .

Now, suppose we are given an arbitrary set  $X$  and a complete metric space  $(\bar{Y}, d)$ , and on  $X^{\bar{Y}}$ , we define the uniform metric  $d_\infty$ . We say a set  $\mathcal{F} \subseteq X^{\bar{Y}}$  of functions is **closed under uniform convergence** if for all uniform convergent sequence  $f_n \subseteq \mathcal{F}$ , the limit function  $f$  is also in  $\mathcal{F}$ . There are justified reasons for us to give the premise that  $\bar{Y}$  is complete prior to the definition of the term **closed under uniform convergence**. One reason is that by Theorem 2.6.4, if  $Y$  is not complete, then the extended metric space  $(X^Y, d_\infty)$  is also not complete, which implies the possibility a Cauchy sequence  $f_n$  in  $X^Y$  converge to a function  $f \in X^{\bar{Y}} \setminus X^Y$  where  $\bar{Y}$  is the completion of  $Y$ . For instance, if we let  $Y = \mathbb{R} \setminus \{1\}$  where  $X = \mathbb{R}$ , and let  $f_n(x) = \begin{cases} 0 & \text{if } x \neq 0 \\ 1 + \frac{1}{n} & \text{if } x = 0 \end{cases} \in Y$ , we see that the set  $\mathcal{F} = \{f_n : n \in \mathbb{N}\}$  is "closed under uniform convergence" in the context of  $X^Y$ , but when in fact  $f_n$  uniformly converge to  $f(x) = \begin{cases} 0 & \text{if } x \neq 0 \\ 1 & \text{if } x = 0 \end{cases}$  which is not in  $\mathcal{F}$ . This awkward usage of words can be solved if we define the term **closed under uniform convergence** after the premise that  $Y$  is complete.

Now, given a set of functions  $\mathcal{F} \subseteq X^{\bar{Y}}$ , one can verify that

$$\begin{aligned} \mathcal{F} \text{ is closed under uniform convergence} &\iff (\mathcal{F}, d_\infty) \text{ is complete} \\ &\iff \mathcal{F} \text{ is closed with respect to } (X^{\bar{Y}}, d_\infty) \end{aligned}$$

Let  $\mathcal{G}$  be a galaxy of  $(X^{\bar{Y}}, d_\infty)$ . With multiple ways, we can verify that  $\mathcal{G}$  is closed with respect to  $(X^{\bar{Y}}, d_\infty)$ . Then, acknowledging the space of bounded functions  $B(X, \bar{Y})$  is a galaxy of  $X^{\bar{Y}}$ , we see that  $B(X, \bar{Y})$  is closed under uniform convergence. The statement that  $B(X, \bar{Y})$  is closed under uniform convergence, although already "proved" before as we pointed out the limit of uniform convergent sequence of bounded functions must be bounded, is now in fact actually proved in the sense the term "closed under uniform convergence" is formally given a satisfying definition.

## 2.9 Arzelà–Ascoli Theorem

In this section, we will give a complete proof of Arzelà–Ascoli Theorem for functions from arbitrary compact topological space to arbitrary metric space. Note that in Baby Rudin, Arzelà–Ascoli Theorem are given for functions from compact metric space to metric space. Because Arzelà–Ascoli Theorem are concerned with family of equicontinuous functions, it is crucial for us to give a definition to equicontinuity for functions from topological space to metric space, for the sake of our generalization.

Let  $X, Y$  be metric space. Let  $Z$  be topological space. Let  $\mathcal{F}_X$  be family of functions from  $X$  to  $Y$ , and let  $\mathcal{F}_Z$  be family of functions from  $Z$  to  $Y$ . We say  $\mathcal{F}_Z$  is **pointwise equicontinuous** if

For all  $\epsilon$  and for all  $x$ , there exists a neighborhood  $U_x$  such that  
 $d_Y(f(x), f(y)) < \epsilon$  for all  $y \in U_x$

We say  $\mathcal{F}_X$  is **equicontinuous** if

For all  $\epsilon$ , there exists  $\delta$  such that  $d_Y(f(x), f(y)) < \epsilon$  for all  $\delta$ -close  $x, y \in X$   
and all  $f \in \mathcal{F}$ .

It is easy to verify that if  $\mathcal{F}_X$  is equicontinuous, then  $\mathcal{F}_X$  is pointwise equicontinuous. The converse don't always hold true. Say,  $\mathcal{F} = \{n + x^2\}_{n \in \mathbb{N}}$ , the set  $\{n + x^2\}_{n \in \mathbb{N}}$  is clearly pointwise equicontinuous on  $\mathbb{R}$ , and is not equicontinuous on  $\mathbb{R}$ , since no function  $n + x^2$  is uniform continuous on  $\mathbb{R}$ . However, the same set  $\mathcal{F} = \{n + x^2\}$  is equicontinuous on compact domain  $[a, b]$ . This is a general result, as we shall prove below.

### Theorem 2.9.1. (Pointwise Equicontinuous is Uniform on Compact Domain)

Given two metric space  $(X, d_X), (Y, d_Y)$ , and a family  $\mathcal{F}$  of functions from  $X$  to  $Y$  such that

- (a)  $X$  is compact
- (b)  $\mathcal{F}$  is pointwise equicontinuous

Then

$\mathcal{F}$  is equicontinuous

*Proof.* Fix  $\epsilon$ . We wish to

find  $\delta$  such that  $d_X(x, y) < \delta \implies d_Y(f(x), f(y)) \leq \epsilon$  for all  $f \in \mathcal{F}$

Because  $\mathcal{F}$  is pointwise equicontinuous, we know for each  $x \in X$ , there exists  $\delta_x$  such that

$$\forall y \in B_{\delta_x}(x), d_Y(f(x), f(y)) < \frac{\epsilon}{2} \text{ for all } f \in \mathcal{F} \quad (2.20)$$

It is clear that  $\{B_{\frac{\delta_x}{2}}(x) : x \in X\}$  form an open cover of  $X$ . Then because  $X$  is compact, we know

there exists a finite open sub-cover:  $\{B_{\frac{\delta_x}{2}}(x) : x \in X_{\text{finite}}\}$

We claim

$$\delta = \min_{x \in X_{\text{finite}}} \frac{\delta_x}{2} \text{ works}$$

Fix  $y, z \in X : d_X(y, z) < \delta$ . We have to prove

$$d_Y(f(y), f(z)) < \epsilon$$

We know  $y$  must lie in some  $B_{\frac{\delta_x}{2}}(x)$  for some  $x \in X_{\text{finite}}$ . Because  $d_X(y, z) < \frac{\delta_x}{2}$ , we see that  $z$  must lie in  $B_{\delta_x}(x)$ . We now know  $y, z$  are both in  $B_{\delta_x}(x)$ . Then from (2.20), we can now deduce

$$d_Y(f(y), f(z)) \leq d_Y(f(y), f(x)) + d_Y(f(x), f(z)) < \epsilon \text{ (done)}$$

■

The proof above should be a great example why in the discussion of metric space, instead of using sequential definition of compactness, which leads to the beautiful Bolzano-Weierstrass Theorem, some people prefer the open-cover definitions.

Now, we give proof for the Arzelà–Ascoli Theorem.

**Theorem 2.9.2. (Arzelà–Ascoli Theorem)** Given a compact topological space  $(X, \tau)$ , a metric space  $(Y, d_Y)$ , and a family  $\mathcal{F} \subseteq C(X, Y)$  of continuous function

$\mathcal{F}$  is pointwise equicontinuous and  $\{f(x) : f \in \mathcal{F}\}$  has compact closure in  $Y$  for all  $x \in X$   
 $\implies \mathcal{F}$  has a compact closure in  $C(X, Y)$

*Proof.* Fix a sequence  $f_n$  in  $\mathcal{F}$ . We wish to show

$f_n$  has a sub-sequence  $f_{n_k}$  uniformly converge to some  $f : X \rightarrow Y$

First, we prove

there exists a countable set  $P$  such that  $P$  works like a dense set

Because  $\mathcal{F}$  is pointwise equicontinuous, we know for all  $x \in X$

$$\exists U_{x,n}, \forall y \in U_{x,n}, \forall f \in \mathcal{F}, d_Y(f(x), f(y)) < \frac{1}{n} \text{ for each fixed } n \in \mathbb{N}$$

Now, because  $X$  is compact, for each  $n \in \mathbb{N}$ , there exists a finite subset  $P_n \subseteq X$  such that  $\{U_{x,n} : x \in P_n\}$  is a cover of  $X$ . Let  $P = \bigcup_{n \in \mathbb{N}} P_n$ . (done)

Now, we wish to

construct a sub-sequence  $f_{n_k}$  pointwise converge on  $P$

Express  $P = \{p_k\}_{k \in \mathbb{N}}$ . By premise (pointwise image has compact closure), we know there exists a compact set that contain  $\{f_n(p_1)\}_{n \in \mathbb{N}}$ , so by Bolzano-Weierstrass Theorem, there exists a sub-sequence

$$\{f_{g_1(k)}(p_1)\}_{k \in \mathbb{N}} \text{ converge to some point in } Y$$

Now, again by premise and Bolzano-Weierstrass Theorem, there exists a sub-sequence

$$\{f_{g_2 \circ g_1(k)}(p_2)\}_{k \in \mathbb{N}} \text{ converge to some point in } Y$$

Repeatedly doing such, we have

$$\begin{array}{cccc} f_{g_1(1)}(p_1) & f_{g_2 \circ g_1(1)}(p_2) & f_{g_3 \circ g_2 \circ g_1(1)}(p_3) & \cdots \\ f_{g_1(2)}(p_1) & f_{g_2 \circ g_1(2)}(p_2) & f_{g_3 \circ g_2 \circ g_1(2)}(p_3) & \cdots \\ f_{g_1(3)}(p_1) & f_{g_2 \circ g_1(3)}(p_2) & f_{g_3 \circ g_2 \circ g_1(3)}(p_3) & \cdots \\ \vdots & \vdots & \vdots & \ddots \\ \downarrow & \downarrow & \downarrow & \\ y_1 & y_2 & y_3 & \cdots \end{array}$$

Now, let

$$n_k = g_k \circ \cdots \circ g_1(k)$$

Then

$$n_k \text{ is eventually a sub-sequence of } g_m \circ \cdots \circ g_1(k) \text{ for all } m$$

This then implies

$$f_{n_k}(p_m) \rightarrow y_m \text{ for all } p_m \in P \text{ (done)}$$

Next, we show

To prove  $f_{n_k}$  uniformly converge on  $X$ , it suffice to prove  $f_{n_k}$  is uniformly Cauchy on  $X$ .

By premise (pointwise image has compact closure), if  $f_{n_k}$  is uniformly Cauchy, then we know  $f_{n_k}$  pointwise converge to some  $f$ .

Fix  $\epsilon$ . We reduced the problem into

finding  $N$  such that for all  $k > N$ , we have  $d_Y(f_{n_k}(x), f(x)) \leq \epsilon$  for all  $x \in X$

Because  $f_{n_k}$  is uniformly Cauchy, we know there exists  $N$  such that for all  $m, k > M$   $d_Y(f_{n_k}(x), f_{n_m}(x)) \leq \frac{\epsilon}{2}$  for all  $x \in X$ . We claim

such  $N$  works

Let  $k > N$ . Assume  $d_Y(f_{n_k}(x), f(x)) > \epsilon$ . We see that

$$d_Y(f(x), f_{n_m}(x)) \geq d_Y(f(x), f_{n_k}(x)) - d_Y(f_{n_k}(x), f_{n_m}(x)) > \frac{\epsilon}{2} \text{ for all } m > N \text{ CaC (done)}$$

Lastly, we wish to prove

$f_{n_k}$  is uniformly Cauchy

Fix  $\epsilon$ . We wish

to find  $N$  such that  $\forall j, k > N, \forall x \in X, d_Y(f_{n_j}(x), f_{n_k}(x)) \leq \epsilon$

Fix  $m > \frac{3}{\epsilon}$ . Express  $P_m = \{p_1^m, \dots, p_u^m\}$ . Because  $f_{n_k}(p_t^m)$  converge for each  $t \in \{1, \dots, u\}$ , we know

$$\forall t, \exists N_t, d_Y(f_{n_j}(p_t^m), f_{n_k}(p_t^m)) < \frac{\epsilon}{3} \text{ for all } j, k > N_t$$

We claim

$N = \max_t N_t$  works

Fix  $j, k > N$  and  $x \in X$ . We have to show

$$d_Y(f_{n_j}(x), f_{n_k}(x)) \leq \epsilon$$

Because  $\{U_{p_t^m, m}\}$  form an open cover of  $X$ , we know there exists  $t$  such that  $x \in U_{p_t^m, m}$ . We can now deduce

$$d_Y(f_{n_j}(x), f_{n_k}(x)) \leq d_Y(f_{n_j}(x), f_{n_j}(p_t^m)) + d_Y(f_{n_j}(p_t^m), f_{n_k}(p_t^m)) + d_Y(f_{n_k}(p_t^m), f_{n_k}(x)) < \epsilon$$

(done)

### 3.1 Equivalent Definitions for Riemann Integral

In this section, we will give a principal Theorem (Theorem 3.1.1) that can serve as a lemma to prove the equivalency of multiple different definitions of Riemann integral on a compact interval. With this approach, we shall diminish the trouble of getting through miscellaneous minor definitions, where they are all equivalent, with only the difference of taking different tags and partitions of certain pattern, which solely serve as a pedagogical tool to give students a concrete idea of integration.

A caveat will be made clear here: this section concern only the proper Riemann Integral. That is, we only consider the integration of a function bounded on a compact interval. For a treatment of improper integral, see Section ??.

In this section, by a **partition**  $P$  of  $[a, b]$ , we mean a finite set of values  $P = \{a = x_0 \leq x_1 \leq \cdots \leq x_{n_P-1} \leq x_{n_P} = b\}$ . We say the partition  $P'$  is **finer** than  $P$  if  $P \subseteq P'$ . Given a partition  $P$ , we put

$$\begin{cases} M_i = \sup_{[x_{i-1}, x_i]} f(x) \\ m_i = \inf_{[x_{i-1}, x_i]} f(x) \end{cases} \quad \text{and} \quad \begin{cases} U(P, f) = \sum_{i=1}^{n_P} M_i \Delta x_i \\ L(P, f) = \sum_{i=1}^{n_P} m_i \Delta x_i \end{cases} \quad \text{where } \Delta x_i = x_i - x_{i-1}$$

We shall write  $n$  instead of  $n_P$  if no confusion will be made.

The word **norm of partition**  $\|P\|$  is defined by  $\max_{1 \leq i \leq n} \Delta x_i$ . We say  $U(P, f)$  is an **upper sum** of  $f$ . We say the **upper integral**  $\overline{\int_a^b} f dx$  of  $f$  on  $[a, b]$  is  $\inf_P U(P, f)$  where the infimum run through all partitions  $P$  of  $[a, b]$ . The **lower integral**  $\underline{\int_a^b} f dx$  is

defined similarly. We say a function  $f$  is **integrable** on  $[a, b]$  if  $\overline{\int_a^b f dx} = \underline{\int_a^b f dx}$ .

Give close attention to the setting that  $P$  is finite. This is crucial for making the integration operation possible, since if  $P$  is countable and we define  $U(P, f)$  by taking limits for sums, the order of addition can make a difference if the sum does not converge absolutely. This fact is backed by Riemann Rearrangement Theorem (Theorem 3.1.7), of which we will later give a proof.

**Theorem 3.1.1. (Principal for Proving Equivalency of Definitions for Riemann Integral)**

$$\int_a^b f dx \in \mathbb{R} \iff \forall \{P_k\} : \|P_k\| \rightarrow 0, U(P_k, f) - L(P_k, f) \rightarrow 0$$

*Proof.* From right to left is obvious. We prove only

$$\int_a^b f dx \in \mathbb{R} \implies \forall \{P_k\} : \|P_k\| \rightarrow 0, U(P_k, f) - L(P_k, f) \rightarrow 0$$

Fix  $\epsilon$ . We wish to find a positive number  $\beta \in \mathbb{R}^+$  such that  $\forall P : \|P\| \leq \beta, U(P, f) - L(P, f) < \epsilon$ . Because  $\int_a^b f dx \in \mathbb{R}$ , we can let  $W$  be a partition such that

$$U(W, f) - L(W, f) < \frac{\epsilon}{2}$$

Let  $W = \{a = x_0^*, x_1^*, \dots, x_{n_W}^* = b\}$ , and let  $J = \{1, \dots, n_W\}$  be the set of indices of  $W$ . Suppose

$$L = \max_{1 \leq j \leq n_W - 1} \left( \sup_{[x_{j-1}^*, x_{j+1}^*]} f(x) - \inf_{[x_{j-1}^*, x_{j+1}^*]} f(x) \right) \quad (3.1)$$

Notice that if  $L = 0$ , then  $f$  must be constant and the proof become trivial, so we can assume  $L > 0$ . We claim that

$$L\beta n_W \leq \frac{\epsilon}{2} \text{ and } \beta < \min_{j \in J} \Delta x_j$$

suffice so that  $\forall P : \|P\| \leq \beta, U(P, f) - L(P, f) < \epsilon$ . Let  $C = \min_{j \in J} \Delta x_j$ . In other words, we now reduce the problem into proving

$$\|P\| \leq \min\left\{\frac{\epsilon}{2Ln_W}, C\right\} \implies U(P, f) - L(P, f) < \epsilon$$

Let  $I = \{1, \dots, n_P\}$  be the set of indices for  $P$ . Suppose

$$P = \{a = x_0, x_1, \dots, x_{n_P} = b\}$$

We partition  $I$  into

$$\begin{cases} A = \left\{ i \in I : \exists j \in J, [x_{i-1}, x_i] \subseteq [x_{j-1}^*, x_j^*] \right\} \\ B = I \setminus A \end{cases}$$

We now have

$$U(P, f) - L(P, f) = \sum_{i \in A} (M_i - m_i) \Delta x_i + \sum_{i \in B} (M_i - m_i) \Delta x_i \quad (3.2)$$

Because for each  $i \in A$ , there is a unique corresponding  $j \in J$  such that  $[x_{i-1}, x_i] \subseteq [x_{j-1}^*, x_j^*]$ , we have

$$\sum_{i \in A} (M_i - m_i) \Delta x_i \leq \sum_{j \in J} (M_j^W - m_j^W) \Delta x_j^* = U(W, f) - L(W, f) < \frac{\epsilon}{2} \quad (3.3)$$

Because  $\|P\| \leq C = \min_{j \in J} \Delta x_j$ , we know for each distinct  $i \in B$ , there exists a distinct  $j \in J$  such that  $[x_{i-1}, x_i] \subseteq [x_{j-1}^*, x_{j+1}^*]$ , so by definition of  $L$  (Equation 3.1), we have

$$\sum_{i \in B} (M_i - m_i) \Delta x_i \leq L \sum_{i \in B} \Delta x_i \leq L n_W \|P\| \leq \frac{\epsilon}{2} \quad (3.4)$$

Combining Equation 3.2, Equation 3.3 and Equation 3.4, we now see

$$U(P, f) - L(P, f) < \epsilon \text{ (done)}$$

■

Recall that we say a series  $\sum_{n=1}^{\infty} a_n$  **absolutely converge** if  $\sum_{n=1}^{\infty} |a_n|$  converge. We can show that a series converges if it absolutely converges by proving it is Cauchy. In this section, by a **permutation on**  $\mathbb{N}$ , we mean a bijective function  $\sigma$  from  $\mathbb{N}$  to  $\mathbb{N}$ . Another two important terminologies are the followings. We say that  $\sum_{n=1}^{\infty} a_n$  **unconditionally converge** if for all permutation  $\sigma : \mathbb{N} \rightarrow \mathbb{N}$ , the series  $\sum_{n=1}^{\infty} a_{\sigma(n)}$  converge to the same number. We say  $\sum_{n=1}^{\infty} a_n$  **conditionally converge** if it converge but not unconditionally.

In our treatment, Riemann Rearrangement Theorem will be split into 4 parts. The summary is at Theorem 3.1.7. The first part (Theorem 3.1.2) states that the limit an absolutely convergent series remain the same under any permutations. The proof for the first part (Theorem 3.1.2) may seem technical, but the essence is quite easy to

remember. Just "see" that

$$\begin{aligned} \left| \sum_{k=1}^{\infty} a_{\sigma(k)} - L \right| &\leq \left| \sum_{i < M} a_i - L + \sum_{i \geq M} a_i \right| \\ &\leq \left| \sum_{i < M} a_i - L \right| + \sum_{i \geq M} |a_i| \rightarrow 0 \text{ as } M \rightarrow \infty \end{aligned}$$

### Theorem 3.1.2. (Riemann Rearrangement Theorem, Part 1)

$$\sum_{k=1}^{\infty} a_k \text{ absolutely converge} \implies \sum_{k=1}^{\infty} a_k \text{ unconditionally converge}$$

*Proof.* Suppose  $\sum_{k=1}^{\infty} |x_k|$  converge. Let  $\sum_{k=1}^{\infty} x_k = L$ . Fix permutation  $\sigma : \mathbb{N} \rightarrow \mathbb{N}$ . We wish to prove

$$\sum_{k=1}^{\infty} x_{\sigma(k)} = L$$

Fix  $\epsilon$ . We reduce the problem into

$$\text{finding } N \text{ such that } \forall n > N, \left| \sum_{k=1}^n x_{\sigma(k)} - L \right| < \epsilon$$

Because both  $\sum_{k=1}^{\infty} x_k$  and  $\sum_{k=1}^{\infty} |x_k|$  converge by premise. We know there exists  $M$  such that

$$\forall n > M, \left| \sum_{k=1}^n x_k - L \right| < \frac{\epsilon}{2} \text{ and } \sum_{k=n}^{\infty} |x_k| < \frac{\epsilon}{2} \quad (3.5)$$

Let

$$I = \sigma^{-1}(\{1, \dots, M\}) \text{ and } N = \max I$$

We claim

such  $N$  works

To prove our claim, fix  $n > N$ . We wish to show

$$\left| \sum_{k=1}^n x_{\sigma(k)} - L \right| < \epsilon$$

Let  $I_n = \{1, \dots, n\}$ . Observe that

$$\left| \sum_{k=1}^n x_{\sigma(k)} - L \right| = \left| \sum_{k \in I_n \setminus I} x_{\sigma(k)} + \sum_{k \in I} x_{\sigma(k)} - L \right| \quad (3.6)$$

Notice that  $k \notin I \implies \sigma(k) > M$ . Then by definition of  $M$  (Equation 3.5), we have

$$\left| \sum_{k \in I_n \setminus I} x_{\sigma(k)} \right| \leq \sum_{k \in I_n \setminus I} |x_{\sigma(k)}| \leq \sum_{j>M}^{\infty} |x_j| < \frac{\epsilon}{2} \quad (3.7)$$

Notice that  $\sigma[I] = \{1, \dots, M\}$ . Then also by definition of  $M$  (Equation 3.5), we have

$$\left| \sum_{k \in I} x_{\sigma(k)} - L \right| = \left| \sum_{j=1}^M x_j - L \right| < \frac{\epsilon}{2} \quad (3.8)$$

Then by inequalities Equation 3.6, Equation 3.7 and Equation 3.8, we now have

$$\begin{aligned} \left| \sum_{k=1}^n a_{\sigma(k)} - L \right| &= \left| \sum_{k \in I_n \setminus I} x_{\sigma(k)} + \sum_{k \in I} x_{\sigma(k)} - L \right| \\ &\leq \left| \sum_{k \in I_n \setminus I} x_{\sigma(k)} \right| + \left| \sum_{k \in I} x_{\sigma(k)} - L \right| \\ &< \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \text{ (done)} \end{aligned}$$

■

The second, third and forth parts (Theorem 3.1.4, Theorem 3.1.5 and Theorem 3.1.6), respectively states that if a series converge but not absolutely, then the limit value can be changed to any real number, infinite, negative infinite and even jumping-ly diverges.

The detail of the proof is very tedious and cumbersome, while the essence is easy to understand. The only two tools for proving Theorem 3.1.4, Theorem 3.1.5 and Corollary 3.1.6, is Lemma 3.1.3 and the fact  $\sum a_k \rightarrow L \implies a_k \rightarrow 0$ . If any part of the proof can be considered interesting, I believe it lies in that of Lemma 3.1.3, where one split the series  $\sum a_k$  into two  $\sum a_k^+$ ,  $\sum a_k^-$ , and shows that they must both diverge.

**Lemma 3.1.3. (Intrinsic Structure of Series that Converge but not Absolutely)**

Let  $f^+ : \mathbb{N} \rightarrow \mathbb{N}$  and  $f^- : \mathbb{N} \rightarrow \mathbb{N}$  satisfy that  $\{a_{f^+(n)}\}$  contain all and only positive terms

of  $\{a_n\}$  and  $\{a_{f^-(n)}\}$  contain all and only negative terms. If  $\sum_{k=1}^{\infty} a_k$  converge but not absolutely, then for each  $\alpha \in \mathbb{R}^+$  and  $n \in \mathbb{N}$ , there exists  $u_n > n$  and  $t_n > n$  such that

$$\sum_{n \leq k \leq u_n} a_{f^+(k)} > \alpha \text{ and } \sum_{n \leq k \leq t_n} a_{f^-(k)} < -\alpha$$

*Proof.* Let  $a_n^+ = \max\{0, a_n\}$  and  $a_n^- = \min\{0, a_n\}$ . It is easy to check  $\forall n \in \mathbb{N}, a_n = a_n^+ + a_n^-$ . Because  $\sum_{k=1}^{\infty} a_k$  converge but not absolutely, we know

$$\begin{cases} \sum_{k=1}^{\infty} a_k^+ \rightarrow \infty \\ \sum_{k=1}^{\infty} a_k^- \rightarrow -\infty \end{cases} \quad (3.9)$$

This is true because if both of them converge then  $\sum_{k=1}^{\infty} |a_k|$  converges and if only one of them converge then  $\sum_{k=1}^{\infty} a_k$  diverges.

Because of Equation 3.9, we know

$$\begin{cases} \sum_{k=1}^{\infty} a_{f^+(k)} \rightarrow \infty \\ \sum_{k=1}^{\infty} a_{f^-(k)} \rightarrow -\infty \end{cases}$$

The result then follow, since

$$\forall n \in \mathbb{N}, \sum_{k \geq n} a_{f^+(k)} \nearrow \infty \text{ and } \sum_{k \geq n} a_{f^-(k)} \searrow -\infty$$

■

**Theorem 3.1.4. (Riemann Rearrangement Theorem, Part 2)** If  $\sum_{k=1}^{\infty} a_k$  converge but not absolutely, then there exists permutations  $\sigma_{\infty}, \sigma_{-\infty} : \mathbb{N} \rightarrow \mathbb{N}$  such that  $\sum_{k=1}^{\infty} a_{\sigma_{\infty}(k)} \rightarrow \infty$  and  $\sum_{k=1}^{\infty} a_{\sigma_{-\infty}(k)} \rightarrow -\infty$ .

*Proof.* We wish

$$\text{to construct } \sigma_{\infty} : \mathbb{N} \rightarrow \mathbb{N} \text{ such that } \sum_{k=1}^{\infty} a_{\sigma_{\infty}(k)} \rightarrow \infty$$

Using Lemma 3.1.3, construct  $\sigma_{\infty} : \mathbb{N} \rightarrow \mathbb{N}$  as follows. Let  $p_n$  be a sequence of natural number such that for each  $n \in \mathbb{N}$ ,  $p_{n+1}$  is the smallest natural number such that

$$\sum_{k=p_n+1}^{p_{n+1}} a_{f^+(k)} > 3 \text{ and } p_1 = 0 \quad (3.10)$$

Similarly, let  $q_n$  be a sequence of natural number such that for each  $n \in \mathbb{N}$ ,  $q_{n+1}$  is the smallest natural number such that

$$\sum_{k=q_n+1}^{q_{n+1}} a_{f^-(k)} < -1 \text{ and } q_1 = 0 \quad (3.11)$$

Notice that the definition of  $p_n$  and  $q_n$  (Equation 3.10, Equation 3.11) are done recursively. Now, recursively define  $\sigma_\infty$  to follow the order

$$\begin{aligned} & f^+(p_1 + 1), \dots, f^+(p_2), f^-(q_1 + 1), \dots, f^-(q_2) \\ \longrightarrow & f^+(p_2 + 1), \dots, f^+(p_3), f^-(q_2 + 1), \dots, f^-(q_3), f^+(p_3 + 1), \dots \end{aligned}$$

If there exists  $k \in \mathbb{N}$  such that  $a_k = 0$ , which is not in the range  $f^+[\mathbb{N}] \cup f^-[\mathbb{N}]$ , we can merge these zero term into our  $\sigma_\infty$  by putting them in terms of even order. This way, our  $\sigma_\infty$  then become bijective, a permutation.

We claim

such  $\sigma_\infty$  works

Recall the definition of  $p_n$  (Equation 3.10) is that for each  $n \in \mathbb{N}$ ,  $p_{n+1}$  is the smallest natural number such that

$$\sum_{k=p_n+1}^{p_{n+1}} a_{f^+(k)} > 3$$

Also recall the similarly defined  $q_n$ . This tell us

$$\sum_{k=p_n+q_n+1}^{p_{n+1}+q_{n+1}} a_{\sigma_\infty(k)} \rightarrow 2 \text{ as } n \rightarrow \infty$$

where

$$\sum_{k=p_n+q_n+1}^{p_{n+1}+q_n} a_{\sigma_\infty(k)} \rightarrow 3 \text{ and } \sum_{k=p_{n+1}+q_{n+1}}^{p_{n+1}+q_{n+1}} a_{\sigma_\infty(k)} \rightarrow -1 \text{ as } n \rightarrow \infty$$

With this, it is easy to verify  $\sum_{k=1}^{\infty} a_{\sigma_\infty(k)} \rightarrow \infty$  (done) . The construction of  $\sigma_{-\infty}$  and the proof for its validity is done similarly. ■

**Theorem 3.1.5. (Riemann Rearrangement Theorem, Part 3)** If  $\sum_{k=1}^{\infty} a_k$  converges but not absolutely, then for all  $[L, M] \subseteq \mathbb{R}$ , there exists a permutation  $\sigma : \mathbb{N} \rightarrow \mathbb{N}$  such that  $\liminf_{n \rightarrow \infty} \sum_{k=1}^n a_{\sigma(k)} = L$  and  $\limsup_{n \rightarrow \infty} \sum_{k=1}^n a_{\sigma(k)} = M$ .

*Proof.* We wish

to construct a working  $\sigma$

The construction of  $\sigma$  is similar to that of  $\sigma_\infty$  in Theorem 3.1.4. WOLOG, let  $M > 0$ . Let  $p_1 = 0$ , and let  $p_2$  be the smallest natural number such that

$$\sum_{k=1}^{p_2} a_{f^+(k)} > M \text{ and } p_1 = 0$$

Next, define  $q_1 = 0$  and let  $q_2$  be the smallest natural number such that

$$\sum_{k=1}^{p_2} a_{f^+(k)} + \sum_{k=1}^{q_2} a_{f^-(k)} < L$$

Then, let  $p_3$  be the smallest natural number such that

$$\sum_{k=1}^{p_3} a_{f^+(k)} + \sum_{k=1}^{q_2} a_{f^-(k)} > M$$

Recursively do such. We get two sequences  $\{p_n\}, \{q_n\}$  of natural number such that for all  $n \in \mathbb{N}$ ,  $p_{n+1}$  is the smallest natural number such that

$$\sum_{k=1}^{p_{n+1}} a_{f^+(k)} + \sum_{k=1}^{q_n} a_{f^-(k)} > M$$

and for all  $n \in \mathbb{N}$ ,  $q_{n+1}$  is the smallest natural number such that

$$\sum_{k=1}^{p_{n+1}} a_{f^+(k)} + \sum_{k=1}^{q_{n+1}} a_{f^-(k)} < L$$

Them, recursively define  $\sigma$  to follow the order

$$\begin{aligned} & f^+(p_1 + 1), \dots, f^+(p_2), f^-(q_1 + 1), \dots, f^-(q_2) \\ \longrightarrow & f^+(p_2 + 1), \dots, f^+(p_3), f^-(q_2 + 1), \dots, f^-(q_3), f^+(p_3 + 1), \dots \end{aligned}$$

Again, merge in the zero terms like in Theorem 3.1.4. The proof for the claim **such  $\sigma$  works** is easy to verify knowing  $a_{\sigma(k)} \rightarrow 0$  **(done)** ■

**Corollary 3.1.6. (Riemann Rearrangement Theorem, Part 4)** If  $\sum_{k=1}^{\infty} a_k$  converges but not absolutely, then for all  $L \in \mathbb{R}$ , there exists a permutation  $\sigma$  such that  $\sum_{k=1}^{\infty} a_{\sigma(k)} = L$

**Theorem 3.1.7. (Summary of Riemann Rearrangement Theorem)** If  $\sum_{k=1}^{\infty} a_k$  converge, then

$$\sum_{k=1}^{\infty} a_k \text{ absolutely converges} \iff \sum_{k=1}^{\infty} a_k \text{ unconditionally converges}$$

*Proof.* ( $\longrightarrow$ )

This is Theorem 3.1.2.

( $\longleftarrow$ )

The fact that the contraposition of this statement is true is implied by any of Theorem 3.1.4, Theorem 3.1.5 and Corollary 3.1.6. ■

## 3.2 Product, Quotient and Chain Rule

This section concern mostly the computation of actual value of the derivative and integral of function. With this in mind, we first prove the product and quotient rules for derivative of  $\mathbb{R}$  to  $\mathbb{R}$  functions taught in most Calculus 1 classes. The proofs for the laws are easy, as it require no ingenious idea but ability to manipulate the limit symbol. However, without philosophical comments, we left an graph for geometric intuition for product rule. There are also graphs for geometric intuition for quotient rule on Internet, but we won't put it here as it require more than subtle work to understand the graph.

Geometric illustration of a proof of the product rule  $\square$

### Theorem 3.2.1. (Product Rule and Quotient Rule for Real to Real Function)

Suppose  $f$  and  $g$  is differentiable at  $x$ , and  $g'(x) \neq 0$ . We have

(a)  $(fg)'(x) = f'(x)g(x) + f(x)g'(x)$  (Product Rule)

(b)  $\left(\frac{f}{g}\right)'(x) = \frac{f'(x)g(x) - f(x)g'(x)}{(g(x))^2}$  (Quotient Rule)

*Proof.* Compute

$$\begin{aligned}
 (fg)'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x)}{h} \\
 &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x+h) + f(x)g(x+h) - f(x)g(x)}{h} \\
 &= \lim_{h \rightarrow 0} \left( g(x+h) \right) \frac{f(x+h) - f(x)}{h} + \left( f(x) \right) \frac{g(x+h) - g(x)}{h} \\
 &= g(x)f'(x) + f(x)g'(x)
 \end{aligned}$$

Compute

$$\begin{aligned}
\left(\frac{f}{g}\right)'(x) &= \lim_{h \rightarrow 0} \frac{\frac{f(x+h)}{g(x+h)} - \frac{f(x)}{g(x)}}{h} \\
&= \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x+h)}{hg(x+h)g(x)} \\
&= \lim_{h \rightarrow 0} \left( \frac{1}{g(x+h)g(x)} \right) \cdot \left( \frac{f(x+h)g(x) - f(x)g(x) + f(x)g(x) - f(x)g(x+h)}{h} \right) \\
&= \lim_{h \rightarrow 0} \left( \frac{1}{g(x+h)g(x)} \right) \cdot \left( (g(x)) \frac{f(x+h) - f(x)}{h} + (f(x)) \frac{g(x) - g(x+h)}{h} \right) \\
&= \left( \frac{1}{(g(x))^2} \right) \cdot \left( (g(x)f'(x)) - f(x)g'(x) \right) = \frac{f'(x)g(x) - f(x)g'(x)}{(g(x))^2}
\end{aligned}$$

■

Even a year has past, I can still remember what happened in the first class of Vector Analysis last year. The professor asked: "What is derivative?". A lot of answers emerge, from extremely formal and abstract like  $\lim_{h \rightarrow 0} \frac{f(x+h)-f(x)}{h}$  to those following geometric intuition like tangent line. Everyone gave a correct answer, but none of them philosophically satisfy the requirement of the question from the professor. Then, he stated: "Derivative is exactly linear approximation", and stated on black board the most general definition:

**Definition 3.2.2. (Definition of Differential)** Given two normed space  $V, W$  and an open subset  $U \subseteq V$ , we say a function  $f : U \rightarrow W$  is **differentiable at  $x$**  if there exists a bounded linear operator  $A : V \rightarrow W$  such that

$$\lim_{h \rightarrow 0} \frac{\|f(x+h) - f(x) - A(h)\|_W}{\|h\|_V} = 0$$

and we say the bounded linear map  $A$  is the **(total) derivative** of  $f$  at  $x$ .

If one put the key words "proof for chain rule" in Google search box, just like the situation in my classes, lots of rigorous proof emerge, but none of them is philosophical satisfying. For this reason, I shall give a proof of chain rule for real to real function based on the concept of linear approximation.

In Baby Rudin, derivative of a real to real function  $f$  is defined by

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$$

Immediately from this definition, we can derive a linear approximation  $P$  of  $f$  at  $a$  by setting

$$P(x) = f(a) + f'(a)(x - a)$$

Then, we see if we set  $R(x) = f(x) - P(x)$  as the error (or the remainder) of the approximation, then trivially we have the behavior

$$R(x) \rightarrow 0 \text{ as } x \rightarrow a$$

what behavior of  $R(x)$  that give  $P$  the name approximation is

$$\frac{R(x)}{x - a} \rightarrow 0 \text{ as } x \rightarrow a$$

The difference between the two behaviors is symbolically apparent, yet without geometric help, it may be difficult to precisely describe how insignificant the first behavior is compared to the second behavior. For this, observe that any function  $g$  that converge to  $f(a)$  at  $a$  satisfy the first behavior, yet only a few satisfy the second. One can easily verify that the only linear  $\mathbb{R}$  to  $\mathbb{R}$  function that satisfy the second behavior is  $P(x) = f(a) + f'(a)(x - a)$ . Geometrically, this means that  $R(x) = o(f'(x)dx)$  as  $x \rightarrow a$ .

**Theorem 3.2.3. (Chain Rule for  $\mathbb{R}$  to  $\mathbb{R}$  function)** Suppose  $g$  is differentiable at  $a$  and  $f$  is differentiable at  $g(a)$ . We have

$$(f \circ g)'(a) = f'(g(a))g'(a)$$

*Proof.* Define the remainders  $R_{f(g(a))}(x)$  and  $R_{g(a)}(x)$  by

$$\begin{cases} R_{f(g(a))}(x) = f(x) - f(g(a)) - f'(g(a))(x - g(a)) \\ R_{g(a)}(x) = g(x) - g(a) - g'(a)(x - a) \end{cases}$$

Compute

$$(f \circ g)'(a) = \lim_{x \rightarrow a} \frac{f(g(x)) - f(g(a))}{x - a} \tag{3.12}$$

$$= \lim_{x \rightarrow a} \frac{R_{f(g(a))}(g(x)) + f'(g(a))(g(x) - g(a))}{x - a} \tag{3.13}$$

Notice that because  $x \rightarrow a \implies g(x) \rightarrow g(a)$ , we have

$$\lim_{x \rightarrow a} \frac{R_{f(g(a))}(g(x))}{x - a} = \lim_{x \rightarrow a} \frac{R_{f(g(a))}(g(x))}{g(x) - g(a)} \cdot \frac{g(x) - g(a)}{x - a} = 0 \cdot g'(x) = 0 \tag{3.14}$$

Notice that the above deduction (Equation 3.14) is quite informal for two reasons: First, it may happen that  $g(x) = g(a)$  locally. Second, for some reader it may require a mini proof to verify that  $\frac{R_{f(g(a))}(g(x))}{g(x)-g(a)} \rightarrow 0$  as  $x \rightarrow a$ . These two obstacles for advanced readers should be insignificant.

Getting back to Equation 3.12, by Equation 3.14, we now see

$$(f \circ g)'(a) = \lim_{x \rightarrow a} \frac{f'(g(a))(g(x) - g(a))}{x - a} = f'(g(a))g'(a)$$

which finish the proof. ■

### 3.3 IVT, EVT and MVT

If one wish to understand most of the Theorems after this section, one must first know MVT, for what an important role it cast in the sections after. Logically prior to MVT is IVT. Yet, unlike MVT involve the intrinsic nature of field and limit structure of  $\mathbb{R}$ . IVT can be considered as purely topological in the sense that its proof can be stated almost in the language of topology. There are only two facts (the first are purely topological and the second is very close to purely topological) one need to know to prove IVT.

First, continuous functions map a connected sets to connected set. Second, a set in  $\mathbb{R}$  is connected if and only if it is an interval.

Combining the above two facts, we have the following statement:

**Theorem 3.3.1. (Continuous Real to Real Function Maps Interval to Interval)** as titled.

*Proof.* Consider the fact a continuous function map connected sets to connected sets and the fact a set in  $\mathbb{R}$  is connected if and only if it is an interval. ■

Then, given the necessary constraint (the interval considered is compact) to give the conclusion, we have the famous statement:

**Theorem 3.3.2. (IVT)** Given a continuous function  $f : [a, b] \rightarrow \mathbb{R}$ , for each  $y$  that lies between  $f(a)$  and  $f(b)$ , there exists  $x \in [a, b]$  such that  $f(x) = y$ .

Given the simplicity of the logical deduction, we shall not give a rigorous proof here. However, one can notice that the interval considered in IVT "must be" compact, otherwise the Theorem is invalid. This constraint is in some sense a showcase how the concept of compact really match the description of "smallness (bounded) and rigidness (closed)".

Compared to IVT, another famous MVT is richer in both the results and the proof. Clearly for a logical and economic purpose, we shall first prove the Cauchy MVT.

**Theorem 3.3.3. (Cauchy's MVT)** Given a function  $f : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $f, g$  are differentiable on  $(a, b)$
- (b)  $f, g$  are continuous on  $[a, b]$

There exists  $x \in (a, b)$  such that

$$[f(b) - f(a)]g'(x) = [g(b) - g(a)]f'(x)$$

*Proof.* We wish to find  $x \in (a, b)$  such that

$$[f(b) - f(a)]g'(x) - [g(b) - g(a)]f'(x) = 0$$

Define  $h$  on  $(a, b)$  by

$$h(x) = [f(b) - f(a)]g'(x) - [g(b) - g(a)]f'(x)$$

We reduced our problem into finding  $x \in (a, b)$  such that

$$h(x) = 0$$

Because  $f, g$  are both differentiable on  $(a, b)$ , we know there exists an anti-derivative  $H$  of  $h$  on  $(a, b)$  such that

$$H(x) = [f(b) - f(a)]g(x) - [g(b) - g(a)]f(x)$$

We have  $h = H'$  on  $(a, b)$ . This let us reduce our problem into

finding a local extremum of  $H$  on  $(a, b)$

Because  $f, g$  are both continuous on  $[a, b]$ , we know  $H$  is continuous on  $[a, b]$ . Then by EVT, we know

$$\exists x \in [a, b], H(x) = \max_{t \in [a, b]} H(t) \text{ and } \exists y \in [a, b], H(y) = \min_{t \in [a, b]} H(t)$$

If such  $x, y$  is in  $(a, b)$ , we are done. If not, says that  $x, y$  both are on end points  $a$  or  $b$ . Compute that

$$H(a) = f(b)g(a) - g(b)f(a) = H(b)$$

We see  $H$  is constant on  $[a, b]$ . Then all points in  $(a, b)$  are extremums. (done) ■

**Corollary 3.3.4. (Lagrange's MVT)** Given a function  $f : [a, b] \rightarrow \mathbb{R}$  such that

(a)  $f$  is differentiable on  $(a, b)$

(b)  $f$  is continuous on  $[a, b]$

Then there exists  $x \in (a, b)$  such that

$$f'(x) = \frac{f(b) - f(a)}{b - a}$$

*Proof.* Let  $g(x) = x$  in Cauchy's MVT (Theorem 3.3.3), and we are done. ■

There are two hypotheses in Lagrange's MVT

(a)  $f$  is differentiable on  $(a, b)$

(b)  $f$  is continuous on  $[a, b]$

They are all necessary. The necessity of differentiability on  $(a, b)$  is clear as shown by the canonical example using absolute value. The necessity of continuity on  $[a, b]$  can be shown by the example

$$f(x) = \begin{cases} 1 & \text{if } a < x \leq b \\ 0 & \text{if } x = a \end{cases}$$

**Theorem 3.3.5. (First Mean Value Theorem for Definite Integral)** Given a function  $f : [a, b] \rightarrow \mathbb{R}$  such that

(a)  $f$  is continuous on  $(a, b)$

There exists  $\xi \in (a, b)$  such that

$$\int_a^b f(x)dx = f(\xi) \cdot (b - a)$$

*Proof.* We wish

to find  $\xi \in (a, b)$  such that  $f(\xi) = \frac{\int_a^b f(x)dx}{b-a}$

Define  $\tilde{f} : [a, b] \rightarrow \mathbb{R}$  on  $[a, b]$  by

$$\tilde{f}(x) = \begin{cases} f(x) & \text{if } x \in (a, b) \\ \lim_{t \rightarrow a} f(t) & \text{if } x = a \\ \lim_{t \rightarrow b} f(t) & \text{if } x = b \end{cases} \quad (3.15)$$

Then, because  $\int_a^b f(x)dx = \int_a^b \tilde{f}(x)dx$ , we reduce our problem into

finding  $\xi \in (a, b)$  such that  $\tilde{f}(\xi) = \frac{\int_a^b \tilde{f}(x)dx}{b-a}$

Because  $\tilde{f}$  is continuous on  $[a, b]$  by definition Equation 3.15, by EVT, we know we there exists  $\alpha, \beta \in [a, b]$  such that

$$\tilde{f}(\alpha) = \inf_{x \in [a, b]} \tilde{f}(x) \text{ and } \tilde{f}(\beta) = \sup_{x \in [a, b]} \tilde{f}(x) \quad (3.16)$$

WOLG, suppose  $\alpha \leq \beta$ . Deduce

$$\tilde{f}(\alpha) = \inf_{x \in [a, b]} \tilde{f}(x) \leq \frac{\int_a^b \tilde{f}(x)dx}{b-a} \leq \sup_{x \in [a, b]} \tilde{f}(x) = \tilde{f}(\beta)$$

by IVT, we then know there exists  $\xi \in [\alpha, \beta]$  such that

$$\exists \xi \in [\alpha, \beta], \tilde{f}(\xi) = \frac{\int_a^b \tilde{f}(x)dx}{b-a} \quad (3.17)$$

If  $a < \alpha$  and  $\beta < b$ , our proof is done.

If not, notice that if  $\tilde{f}(\alpha) = \tilde{f}(\beta)$ , then by definition of  $\alpha, \beta$  (Equation 3.16), the proof is trivial since  $\tilde{f}$  is a constant, so we only have to consider when  $\tilde{f}(\alpha) < \tilde{f}(\beta)$ , and we wish to show

$\xi$  can not happen at  $a$  nor  $b$

Assume  $\xi = a$ , WOLG. Because  $\xi \in [\alpha, \beta]$ , we know  $\alpha = a$ . Because  $\tilde{f}(\beta) > \tilde{f}(\alpha)$ , we can find  $\delta$  such that

$$\inf_{x \in [\beta-\delta, \beta]} \tilde{f}(x) \geq \frac{\tilde{f}(\alpha) + 2\tilde{f}(\beta)}{3} \quad (3.18)$$

We then from Equation 3.17 see that

$$\int_a^b \tilde{f}(x)dx = \tilde{f}(\xi)(b-a) = \tilde{f}(\alpha)(b-a) \quad (3.19)$$

Also, we see from definition of  $\alpha$  (Equation 3.16) and Equation 3.18 that

$$\int_a^b \tilde{f}(x)dx = \int_a^{\beta-\delta} \tilde{f}(x)dx + \int_{\beta-\delta}^{\beta} \tilde{f}(x)dx + \int_{\beta}^b \tilde{f}(x)dx \quad (3.20)$$

$$\geq (b-\delta-a)\tilde{f}(\alpha) + \delta \cdot \left(\frac{\tilde{f}(\alpha) + 2\tilde{f}(\beta)}{3}\right) \quad (3.21)$$

$$> (b-\delta-a)\tilde{f}(\alpha) + \delta \cdot \left(\frac{\tilde{f}(\alpha) + \tilde{f}(\beta)}{2}\right) \quad (3.22)$$

$$= \tilde{f}(\alpha)\left(b-a-\frac{\delta}{2}\right) + \tilde{f}(\beta) \cdot \left(\frac{\delta}{2}\right) \quad (3.23)$$

Now, from Equation 3.19 and Equation 3.23, we can deduce

$$\tilde{f}(\alpha)(b-a) > \tilde{f}(\alpha)\left(b-a-\frac{\delta}{2}\right) + \tilde{f}(\beta) \cdot \left(\frac{\delta}{2}\right)$$

Then we can deduce

$$\tilde{f}(\alpha) \cdot \left(\frac{\delta}{2}\right) > \tilde{f}(\beta) \cdot \left(\frac{\delta}{2}\right) \text{ CaC (done)}$$

■

**Theorem 3.3.6. (Second Mean Value Theorem for Definite Integral)** Given functions  $G, \phi : [a, b] \rightarrow \mathbb{R}$  such that

(a)  $G$  is monotonic

(b)  $\phi$  is Riemann-Integrable

Let  $G(a^+) = \lim_{t \rightarrow a^+} G(t)$  and  $G(b^-) = \lim_{t \rightarrow b^-} G(t)$ . Then there exists  $\xi \in (a, b)$  such that

$$\int_a^b G(t)\phi(t)dt = G(a^+) \int_a^{\xi} \phi(t)dt + G(b^-) \int_{\xi}^b \phi(t)dt$$

*Proof.* Define  $f$  on  $[a, b]$  by

$$f(x) = G(a^+) \int_a^x \phi(t)dt + G(b^-) \int_x^b \phi(t)dt$$

We then reduce the problem into

$$\text{finding } \xi \in (a, b) \text{ such that } \int_a^b G(t)\phi(t)dt = f(\xi)$$

By Theorem 3.7.1, we know  $f$  is continuous on  $[a, b]$ . Then by IVT, we can reduce the problem into

$$\text{finding an interval } [c, d] \subseteq (a, b) \text{ such that } \int_a^b G(t)\phi(t) \text{ is between } f(c) \text{ and } f(d)$$

Observe that

$$f(a) = G(b^-) \int_a^b \phi(t)dt \text{ and } f(b) = G(a^+) \int_a^b \phi(t)dt$$

■

### 3.4 Riemann-Stieltjes on Computation

**Theorem 3.4.1. (Change of Variable)** Given two functions  $g, \beta : [A, B] \rightarrow \mathbb{R}$ , a function  $\phi : [A, B] \rightarrow [a, b]$  and two functions  $f, \alpha : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $g = f \circ \phi$  for all  $x \in [a, b]$
- (b)  $\beta = \alpha \circ \phi$  for all  $x \in [a, b]$
- (c)  $\alpha, \beta$  increase respectively on  $[a, b]$  and  $[A, B]$
- (d)  $\phi : [A, B] \rightarrow [a, b]$  is a homeomorphism
- (e)  $\int_a^b f d\alpha$  exist

Then

$$\int_A^B g d\beta = \int_a^b f d\alpha \quad (\text{This implies } \int_A^B g d\beta \text{ exists})$$

*Proof.* Fix  $\epsilon$ . We only wish

to find a partition  $Q$  of  $[A, B]$  such that  $U(Q, g, \beta) - L(Q, g, \beta) < \epsilon$   
and such that  $\int_a^b f d\alpha \in [L(Q, g, \beta), U(Q, g, \beta)]$

Because  $\int_a^b f d\alpha$  exists, we know

$$\text{there exists a partition } P \text{ of } [a, b] \text{ such that } U(P, f, \alpha) - L(P, f, \alpha) < \epsilon \quad (3.24)$$

where, of course,  $\int_a^b f d\alpha \in [L(P, f, \alpha), U(P, f, \alpha)]$ .

Let  $P = \{a = x_0, x_1, \dots, x_n = b\}$ . Because  $\phi$  is a homeomorphism, we can let  $\phi$  be strictly increasing WOLOG.

Define a partition  $Q$  on  $[A, B]$  by

$$Q = \phi^{-1}[P] = \{A = \phi^{-1}(x_0), \phi^{-1}(x_1), \dots, \phi^{-1}(x_n) = B\}$$

Now, because  $\beta = \alpha \circ \phi$  and  $g = f \circ \phi$  for all  $x \in [a, b]$  by premise, and because  $\phi$  is a

homeomorphism, we have

$$\begin{aligned}
U(Q, g, \beta) &= \sum_{k=1}^n \left[ \sup_{t \in [\phi^{-1}(x_{k-1}), \phi^{-1}(x_k)]} g(t) \right] [\beta(\phi^{-1}(x_k)) - \beta(\phi^{-1}(x_{k-1}))] \\
&= \sum_{k=1}^n \left[ \sup_{t \in [\phi^{-1}(x_{k-1}), \phi^{-1}(x_k)]} f \circ \phi(t) \right] [\alpha \circ \phi(\phi^{-1}(x_k)) - \alpha \circ \phi(\phi^{-1}(x_{k-1}))] \\
&= \sum_{k=1}^n \left[ \sup_{t \in [x_{k-1}, x_k]} f(t) \right] (\alpha(x_k) - \alpha(x_{k-1})) = U(P, f, \alpha) \tag{3.25}
\end{aligned}$$

Similarly, we can deduce  $L(Q, g, \beta) = L(P, f, \alpha)$ . Now, from Equation 3.25 and by definition of  $P$  (Equation 3.24), we see

$$\begin{aligned}
U(Q, g, \beta) - L(Q, g, \beta) &= U(P, f, \alpha) - L(P, f, \alpha) < \epsilon \\
\text{and } \int_a^b f d\alpha &\in [L(P, f, \alpha), U(P, f, \alpha)] = [L(Q, g, \beta), U(Q, g, \beta)] \quad (\text{done})
\end{aligned}$$

■

**Theorem 3.4.2. (Reduction of Riemann-Stieltjes Integral: Part 1)** Given two functions  $f, \alpha : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $\alpha$  increase on  $[a, b]$
- (b)  $\alpha$  is differentiable on  $(a, b)$
- (c)  $\lim_{x \rightarrow b^-} \frac{\alpha(x) - \alpha(b)}{x - b}$  exists and  $\lim_{x \rightarrow a^+} \frac{\alpha(x) - \alpha(a)}{x - a}$  exists
- (d)  $\alpha'$  is properly Riemann-Integrable on  $[a, b]$
- (e)  $f$  is bounded on  $[a, b]$

Then

$$\int_a^b f d\alpha \text{ exists} \iff \int_a^b f(x) \alpha'(x) dx \text{ exists and they equal to each other if exists}$$

*Proof.* We wish to prove

$$\overline{\int_a^b f d\alpha} = \overline{\int_a^b f(x) \alpha'(x) dx}$$

Fix  $\epsilon$ . We reduce the problem into proving

$$\left| \overline{\int_a^b f d\alpha} - \overline{\int_a^b f(x) \alpha'(x) dx} \right| < \epsilon$$

Then, because for all partition  $P$  of  $[a, b]$ , we have

$$\begin{aligned} & \left| \overline{\int_a^b f d\alpha} - \overline{\int_a^b f(x) \alpha'(x) dx} \right| \\ & \leq \left| \overline{\int_a^b f d\alpha} - U(P, f, \alpha) \right| - \left| U(P, f, \alpha) - U(P, f \alpha') \right| - \left| U(P, f \alpha') - \overline{\int_a^b f(x) \alpha'(x) dx} \right| \end{aligned}$$

We only wish

$$\begin{aligned} & \text{to find } P \text{ such that } \left| \overline{\int_a^b f d\alpha} - U(P, f, \alpha) \right| < \frac{\epsilon}{3} \\ & \text{and } \left| U(P, f, \alpha) - U(P, f \alpha') \right| < \frac{\epsilon}{3} \text{ and } \left| \overline{\int_a^b f(x) \alpha'(x) dx} - U(P, f \alpha') \right| < \frac{\epsilon}{3} \end{aligned}$$

Because  $f$  is bounded on  $[a, b]$ , we can let  $M = \sup_{x \in [a, b]} |f(x)|$ . Because  $\int_a^b \alpha'(x) dx$  exists, we can let  $P$  satisfy

$$U(P, \alpha') - L(P, \alpha') < \frac{\epsilon}{4M} \quad (3.26)$$

By definition of Riemann Upper sum, we can further refine  $P$  to let  $P$  satisfy

$$\left| \overline{\int_a^b f d\alpha} - U(P, f, \alpha) \right| < \frac{\epsilon}{3} \text{ and } \left| \overline{\int_a^b f(x) \alpha'(x) dx} - U(P, f \alpha') \right| < \frac{\epsilon}{3}$$

It is clear that the statement concerning  $P$  (Equation 3.26) remain valid after refinement of  $P$ . Fix such  $P$ . We now have reduced the problem into proving

$$|U(P, f, \alpha) - U(P, f \alpha')| < \frac{\epsilon}{3}$$

Express  $P$  in the form  $P = \{a = x_0, x_1, \dots, x_n = b\}$ . By MVT (Theorem 3.3.4), we know for all  $k \in \{1, \dots, n\}$  there exists  $t_k \in [x_{k-1}, x_k]$  such that

$$\Delta \alpha_k = \alpha'(t_k) \Delta x_k \quad (3.27)$$

Then, because  $U(P, \alpha') - L(P, \alpha') < \frac{\epsilon}{3M}$  (Equation 3.26), we now see

$$\sum_{k=1}^n |\alpha'(s_k) - \alpha'(t_k)| \Delta x_k < \frac{\epsilon}{3M} \text{ if } s_k \in [x_{k-1}, x_k] \text{ for all } k \in \{1, \dots, n\} \quad (3.28)$$

Then from Equation 3.27, definition of  $M$  and Equation 3.28, we have

$$\begin{aligned}
\left| \sum_{k=1}^n f(s_k) \Delta \alpha_k - \sum_{k=1}^n f(s_k) \alpha'(s_k) \Delta x_k \right| &= \left| \sum_{k=1}^n f(s_k) (\alpha'(s_k) - \alpha'(t_k)) \Delta x_k \right| \\
&\leq \sum_{k=1}^n |f(s_k)| \cdot |\alpha'(s_k) - \alpha'(t_k)| \Delta x_k \\
&\leq M \sum_{k=1}^n |\alpha'(s_k) - \alpha'(t_k)| \Delta x_k \\
&< \frac{\epsilon}{4}
\end{aligned}$$

Then because  $\sum_{k=1}^m f(s_k) \alpha'(s_k) \Delta x_k \leq U(P, f\alpha')$ , we now have

$$\sum_{k=1}^n f(s_k) \Delta \alpha_k < U(P, f\alpha') + \frac{\epsilon}{4} \tag{3.29}$$

Because Equation 3.29 hold true for all choices of  $s_k$ , we have

$$U(P, f, \alpha) < U(P, f\alpha') + \frac{\epsilon}{3}$$

Similarly, we can deduce

$$U(P, f\alpha') < U(P, f, \alpha) + \frac{\epsilon}{3} \text{ (done)}$$

■

**Theorem 3.4.3. (Substitution Law)** Given a function  $\phi : [a, b] \rightarrow [A, B]$  and a function  $f : [A, B] \rightarrow \mathbb{R}$  such that

- (a)  $\phi$  is a homoeomorphism.
- (b)  $\phi$  is differentiable on  $(a, b)$
- (c)  $\int_a^b \phi'(x) dx$  exists.
- (d)  $f$  is integrable on  $[A, B]$

We have

$$\int_a^b f(\phi(x)) \phi'(x) dx = \int_A^B f(u) du$$

*Proof.* Because  $f \circ \phi$  and  $\phi'$  is integrable on  $[a, b]$ , by reduction of Riemann-Stieljes Integral (Theorem 3.4.2), we know

$$\int_a^b (f \circ \phi)(x) \phi'(x) dx = \int_a^b (f \circ \phi)(x) d\phi$$

Let  $\alpha(x) = x$ . Let  $\beta = \alpha \circ \phi$ . Define  $g = f \circ \phi$ . By Change of Variable (Theorem 3.4.1), we now have

$$\int_a^b (f \circ \phi)(x) d\phi = \int_a^b g(x) d\beta = \int_A^B f(x) dx$$

■

### 3.5 Weierstrass approximation Theorem: $[a, b] \rightarrow \mathbb{R}$

**Theorem 3.5.1. (Bernoulli's Inequality)** Given  $r, x \in \mathbb{R}$ , suppose

- (a)  $r \geq 1$
- (b)  $x \geq -1$

Then

$$(1 + x)^r \geq 1 + rx$$

*Proof.* Fix  $r \geq 1$ . We wish

to prove  $(1 + x)^r \geq 1 + rx$  for all  $x \geq -1$

Define  $f : [-1, \infty) \rightarrow \mathbb{R}$  by

$$f(x) = (1 + x)^r - (1 + rx) \tag{3.30}$$

We reduced the problem into

proving  $f(x) \geq 0$  for all  $x \geq -1$

Because  $r \geq 1$  by premise, by definition of  $f(x)$  (Equation 3.30), we see that

$$f(0) = 0, \text{ and } f(-1) = r - 1 \geq 0$$

Notice that by definition of  $f$  (Equation 3.30),  $f(x)$  is clearly differentiable on  $(-1, \infty)$ .

Then, by MVT (Theorem 3.3.4), to prove  $f(x) \geq 0$  on  $(-1, \infty)$ , we only wish

to prove  $f'(x) \geq 0$  for all  $x > 0$  and  $f'(x) \leq 0$  for all  $x \in (-1, 0)$

Compute  $f'$

$$\begin{aligned} f'(x) &= r(1 + x)^{r-1} - r \\ &= r\left((1 + x)^{r-1} - 1\right) \end{aligned}$$

Because  $r \geq 1$ , we can deduce

$$x > 0 \implies (1 + x)^{r-1} \geq 1 \implies f'(x) = r\left((1 + x)^{r-1} - 1\right) \geq 0$$

and deduce

$$x \in (-1, 0) \implies 1 + x \in (0, 1) \implies (1 + x)^{r-1} \leq 1 \implies f'(x) = r\left((1 + x)^{r-1} - 1\right) \leq 0$$

(done) ■

In this section, notation  $\mathcal{C}([a, b])$  means the set of **real-valued continuous function on  $[a, b]$** .

**Theorem 3.5.2. (Weierstrass approximation Theorem:**  $[a, b] \rightarrow \mathbb{R}$ ) Let  $\mathbb{R}[x]|_{[a, b]}$  be the space of polynomials on  $[a, b]$  with real coefficient. We have

$$\mathbb{R}[x]|_{[a, b]} \text{ is dense in } \left( \mathcal{C}([a, b]), \|\cdot\|_\infty \right)$$

*Proof.* WOLG, we can let  $[a, b] = [0, 1]$ . The reason we can assume such is explained at last. Now, let  $f : [0, 1] \rightarrow \mathbb{R}$  be a continuous function. Fix  $\epsilon$ . We only wish

$$\text{to find } P \in \mathbb{R}[x]|_{[0, 1]} \text{ such that } \|f - P\|_\infty < \epsilon$$

Define  $\tilde{f} \in \mathcal{C}([0, 1])$  by

$$\tilde{f}(x) = f(x) - f(0) - x[f(1) - f(0)] \quad (3.31)$$

It is easy to check  $\tilde{f}$  is continuous. We first prove that

$$(\tilde{f}(x) - f(x)) \in \mathbb{R}[x]|_{[0, 1]}$$

By definition of  $\tilde{f}$  (Equation 3.31), we see

$$\tilde{f}(x) - f(x) = (f(0) - f(1))x - f(0) \in \mathbb{R}[x]|_{[0, 1]} \text{ (done)}$$

This reduce our problem into

$$\text{finding } P \in \mathbb{R}[x]|_{[0, 1]} \text{ such that } \|\tilde{f} - P\|_\infty < \epsilon$$

Notice that by definition of  $\tilde{f}$  (Equation 3.31), we have

$$\tilde{f}(0) = 0 = \tilde{f}(1)$$

Then, we can expand the definition of  $\tilde{f}$  by

$$\tilde{f}(x) = \begin{cases} \tilde{f}(x) & \text{if } x \in [0, 1] \\ 0 & \text{if } x \notin [0, 1] \end{cases} \quad (3.32)$$

This makes  $\tilde{f}$  uniformly continuous on  $\mathbb{R}$ , since  $\tilde{f}$  is uniformly continuous on  $[0, 1]$  and  $[0, 1]^c$ . Now, for each  $n \in \mathbb{N}$ , define  $Q_n \in \mathbb{R}[x]$  by

$$Q_n = c_n(1 - x^2)^n \text{ where } c_n \text{ is chosen to satisfy } \int_{-1}^1 Q_n(x) dx = 1 \quad (3.33)$$

Define  $P_n : [0, 1] \rightarrow \mathbb{R}$  by

$$P_n(x) = \int_{-1}^1 \tilde{f}(x+t)Q_n(t)dt$$

We now prove

$$P_n \in \mathbb{R}[x]|_{[0,1]}$$

Because  $\tilde{f}(x) = 0$  for all  $x \notin (0, 1)$  by definition of  $\tilde{f}$  (Equation 3.32), we see that

$$P_n(x) = \int_{-x}^{1-x} \tilde{f}(x+t)Q_n(t)dt \text{ for all } x \in [0, 1] \quad (3.34)$$

Fix  $x \in [0, 1]$ . Now, by change of variable, we see

$$P_n(x) = \int_{-x}^{1-x} \tilde{f}(x+t)Q_n(t)dt = \int_0^1 \tilde{f}(u)Q_n(u-x)du$$

Because  $Q_n$  is a polynomial by definition (Equation 3.33), we can express  $Q_n(u-x)$  by

$$Q_n(u-x) = \sum_{k=0}^m a_k x^k \text{ for some } \{a_0, \dots, a_m\} \text{ depending on } u$$

Then we see

$$P_n(x) = \int_0^1 \tilde{f}(u)Q_n(u-x)du = \sum_{k=0}^m x^k \left( \int_0^1 \tilde{f}(u)a_k du \right)$$

This shows that  $P_n \in \mathbb{R}[x]|_{[0,1]}$   
(done)

Now, because  $\tilde{f}$  is uniformly continuous on  $\mathbb{R}$ , we can fix  $\delta < 1$  such that

$$\forall x, y \in \mathbb{R}, |x-y| < \delta \implies \left| \tilde{f}(x) - \tilde{f}(y) \right| < \frac{\epsilon}{2} \quad (3.35)$$

By definition of  $\tilde{f}$  (Equation 3.32), we know  $\tilde{f}$  is a bounded function. Then we can set  $M$  by

$$M = \sup_{x \in \mathbb{R}} |\tilde{f}(x)|$$

Let  $n$  satisfy

$$4M\sqrt{n}(1-\delta^2)^n < \frac{\epsilon}{2} \quad (3.36)$$

Such  $n$  exists, because  $\delta < 1 \implies \sqrt{n}(1 - \delta^2)^n \rightarrow 0$ . We claim

$$P_n \text{ satisfy } \|\tilde{f} - P_n\|_\infty < \epsilon$$

We first prove

$$c_n < \sqrt{n}$$

By Bernoulli's Inequality (Theorem 3.5.1). Compute

$$\begin{aligned} 1 &= \int_{-1}^1 Q_n(x) dx = c_n \int_{-1}^1 (1 - x^2)^n dx \\ &= 2c_n \int_0^1 (1 - x^2)^n dx \\ &\geq 2c_n \int_0^{\frac{1}{\sqrt{n}}} (1 - x^2)^n dx \\ &\geq 2c_n \int_0^{\frac{1}{\sqrt{n}}} 1 - nx^2 dx = c_n \left( \frac{4}{3\sqrt{n}} \right) > c_n \left( \frac{1}{\sqrt{n}} \right) \end{aligned}$$

This implies

$$\sqrt{n} > c_n \text{ (done)}$$

Because  $\sqrt{n} > c_n$ , by definition of  $Q_n$  (Equation 3.33), we have

$$Q_n(x) < \sqrt{n}(1 - x^2)^n \leq \sqrt{n}(1 - \delta^2)^n \text{ for all } x \text{ such that } \delta \leq |x| \leq 1$$

Fix  $x \in [0, 1]$ . Finally, because

- (a)  $\int_{-1}^1 Q_n(x) dx = 1$  by definition of  $Q_n$  (Equation 3.33)
- (b)  $Q_n(x) = c_n(1 - x^2)^n \geq 0$  for all  $x \in [-1, 1]$
- (c)  $|\tilde{f}(x + t) - \tilde{f}(x)| < \frac{\epsilon}{2}$  for all  $t$  such that  $|t| < \delta$ , by definition of  $\delta$  (Equation 3.36)
- (d)  $Q_n(x) \leq \sqrt{n}(1 - \delta^2)^n$  for all  $x$  such that  $\delta \leq |x| \leq 1$
- (e)  $4M\sqrt{n}(1 - \delta^2)^n < \frac{\epsilon}{2}$  by definition of  $n$  (Equation 3.36)

we have

$$\begin{aligned}
|P_n(x) - \tilde{f}(x)| &= \left| \int_{-1}^1 \tilde{f}(x+t) Q_n(t) dt - \tilde{f}(x) \right| \\
&= \left| \int_{-1}^1 \tilde{f}(x+t) Q_n(t) dt - \tilde{f}(x) \int_{-1}^1 Q_n(t) dt \right| \\
&= \left| \int_{-1}^1 \tilde{f}(x+t) Q_n(t) dt - \int_{-1}^1 \tilde{f}(x) Q_n(t) dt \right| \\
&= \left| \int_{-1}^1 [\tilde{f}(x+t) - \tilde{f}(x)] Q_n(t) dt \right| \\
&\leq \int_{-1}^1 |\tilde{f}(x+t) - \tilde{f}(x)| Q_n(t) dt \\
&= \int_{-1}^1 |\tilde{f}(x+t) - \tilde{f}(x)| Q_n(t) dt \\
&\leq \int_{-1}^{-\delta} 2M Q_n(t) dt + \int_{-\delta}^{\delta} |\tilde{f}(x+t) - \tilde{f}(x)| Q_n(t) dt + \int_{\delta}^1 2M Q_n(t) dt \\
&\leq 2M \left( \int_{-1}^{-\delta} Q_n(t) dt + \int_{\delta}^1 Q_n(t) dt \right) + \int_{-\delta}^{\delta} \left(\frac{\epsilon}{2}\right) Q_n(t) dt \\
&\leq 4M(1-\delta)\sqrt{n}(1-\delta^2)^n + \frac{\epsilon}{2} \\
&\leq 4M\sqrt{n}(1-\delta^2)^n + \frac{\epsilon}{2} < \epsilon
\end{aligned}$$

Because  $x$  is arbitrarily picked from  $[0, 1]$ , we now have  $\|P_n - \tilde{f}\|_{\infty} < \epsilon$  (done)

Lastly, we show

our result can be transplanted to arbitrary  $\mathcal{C}([a, b])$

Let  $[a, b]$  be arbitrary. Fix  $\epsilon$  and  $f \in \mathcal{C}([a, b])$ . We wish

to find  $P \in \mathbb{R}[x]_{[a, b]}$  such that  $\|f - P\|_{\infty} \leq \epsilon$

Define  $g : [0, 1] \rightarrow \mathbb{R}$  by

$$g(x) \triangleq f(a + (b-a)x) \tag{3.37}$$

We know there exists  $P_n : [0, 1] \rightarrow \mathbb{R}$  such that

$$\|P_n - g\|_{\infty} < \epsilon$$

Define  $H_n : [a, b] \rightarrow \mathbb{R}$  by

$$H_n(x) = P_n\left(\frac{x-a}{b-a}\right)$$

Because  $P_n$  is a real polynomial on  $[0, 1]$ , we know  $H_n$  is a real polynomial on  $[a, b]$ . We now claim

such  $H_n$  works

Fix  $x \in [a, b]$ . Observe

$$\begin{aligned} |f(x) - H_n(x)| &= \left| f(x) - P_n\left(\frac{x-a}{b-a}\right) \right| \\ &= \left| g\left(\frac{x-a}{b-a}\right) - P_n\left(\frac{x-a}{b-a}\right) \right| < \epsilon \text{ (done)} \end{aligned}$$

■

It is at now, we will show that every real-valued continuous functions on  $[a, b]$  can be approximated by polynomials with rational coefficient. This fact enable our computer to more easily approximate real-valued continuous function on  $[a, b]$ .

Note that since  $\mathcal{C}([a, b])$  is a separable metric space, we can show that  $\mathcal{C}([a, b])$  has cardinality of at most continuum  $\mathfrak{c}$ .

**Theorem 3.5.3.** (The space  $\mathbb{Q}[x]|_{[a,b]}$  is dense in  $(\mathcal{C}([a, b]), \|\cdot\|_\infty)$ , thus  $\mathcal{C}([a, b])$  is separable)

$(\mathcal{C}([a, b]), \|\cdot\|_\infty)$  is separable

*Proof.* Because  $\mathbb{Q}[x]|_{[a,b]}$  is countable, to show  $\mathcal{C}([a, b])$  is separable, we only wish to show

$\mathbb{Q}[x]|_{[a,b]}$  is dense in  $\mathcal{C}([a, b])$

Because  $\mathbb{R}[x]|_{[a,b]}$  is dense in  $\mathcal{C}([a, b])$ , we reduce our problem into proving

$\mathbb{Q}[x]|_{[a,b]}$  is dense in  $\mathbb{R}[x]|_{[a,b]}$

Fix  $\epsilon$  and  $P \in \mathbb{R}[x]|_{[a,b]}$ . We must

find  $Q \in \mathbb{Q}[x]|_{[a,b]}$  such that  $\|Q - P\|_\infty \leq \epsilon$

Express  $P(x) = \sum_{k=0}^n r_k x^k$ . Let  $M > \max\{|a|, |b|\}$ . Because  $\mathbb{Q}$  is dense in  $\mathbb{R}$ , we know there exists  $c_k \in \mathbb{Q}$  such that  $|c_k - r_k| < \frac{\epsilon}{(n+1)M^n}$ . We claim

$$Q(x) = \sum_{k=0}^n c_k x^k \text{ works}$$

Fix  $x \in [a, b]$ . See

$$\begin{aligned} |P(x) - Q(x)| &= \left| \sum_{k=0}^n (c_k - r_k) x^k \right| \\ &\leq \sum_{k=0}^n |c_k - r_k| \cdot |x|^k \\ &\leq \sum_{k=0}^n |c_k - r_k| \cdot M^k \\ &\leq (M^n) \sum_{k=0}^n |c_k - r_k| \\ &< M^n(n+1) \left( \frac{\epsilon}{(n+1)M^n} \right) = \epsilon \text{ (done)} \end{aligned}$$

■

### 3.6 The Stone-Weierstrass Theorem

Recall that a **vector space over a field**  $\mathbb{F}$  is a set  $V$  equipped with **vector addition**  $+: V \times V \rightarrow V$  and **scalar multiplication** such that

- (a)  $(V, +)$  is an abelian group.
- (b) Scalar multiplication is compatible with field multiplication:  $((ab)v = a(bv))$
- (c) Scalar multiplication is distributive:  $((a+b)v = av + bv$  and  $a(v+w) = av + aw)$

There are many ways to define the term **algebra over a field**  $\mathbb{F}$ . One can exhaust all the laws an algebra should obey. In short, an **algebra over a field**  $\mathbb{F}$  (or  **$\mathbb{F}$ -algebra**) is a set  $(A, +, \cdot)$  equipped scalar multiplication over  $\mathbb{F}$  such that

- (a) Multiplication  $\cdot$  is distributive with respect to  $+$
- (b)  $(A, +)$  and scalar multiplication form a vector space.
- (c) Scalar multiplication and vector multiplication  $\cdot$  is compatible:  $((av) \cdot (bw) = ab(v \cdot w))$

Given an arbitrary set  $E$  and a field  $\mathbb{F}$ , let  $A$  be the set of all functions from  $E$  to  $\mathbb{F}$ . The following is a list of some algebra

- (a)  $(\mathbb{R}^3, \text{cross product})$  over  $\mathbb{R}$
- (b)  $(\mathbb{C}, \text{complex multiplication})$  over  $\mathbb{C}$
- (c)  $(\mathbb{Q}[x], \text{function multiplication})$  over  $\mathbb{Q}$
- (d)  $(\text{Functions from } E \text{ to } \mathbb{F}, \text{function multiplication})$  over  $\mathbb{F}$
- (e)  $(\text{Continuous functions from } (E, \tau) \text{ to } \mathbb{C}, \text{function multiplication})$  over  $\mathbb{C}$
- (f)  $(\text{Linear transformation from } V \text{ to } V, \text{composition})$  over  $\mathbb{F}$  where  $V$  is over  $\mathbb{F}$
- (g)  $(M_n(\mathbb{F}), \text{matrix multiplication})$  over  $\mathbb{F}$

Note that  $B = (\text{continuous functions from } \mathbb{C} \text{ to } \mathbb{C}, \text{composition})$  over  $\mathbb{C}$  is not an algebra, even though  $B$  is both a vector space and a ring. ( $\because$  scalar multiplication and multiplication are not compatible).

It is at here we shall introduce some general terminologies. Given an arbitrary set  $E$ , a field  $\mathbb{F}$  and a point  $x \in E$ , we say a family  $\mathcal{F}$  of functions from  $E$  to  $\mathbb{F}$  **vanish at**  $x$  if for all  $f \in \mathcal{F}$ , we have  $f(x) = 0$ . We say  $\mathcal{F}$  **separate points** in  $E$  if for all  $x_2 \neq x_1 \in E$ , there exists  $f \in \mathcal{F}$  such that  $f(x_2) \neq f(x_1)$ .

## 3.7 FTC

**Theorem 3.7.1. (Fundamental Theorem of Calculus: Part 1)** Suppose a function  $f : [a, \infty) \rightarrow \mathbb{R}$  satisfy

$f$  is proper-Riemann integrable on  $[a, b]$  for all  $b > a$

If we set  $F : [a, \infty) \rightarrow \mathbb{R}$

$$F(x) = \int_a^x f(t)dt$$

Then

- (a)  $F$  is continuous on  $[a, \infty)$
- (b)  $F$  is differentiable at  $x_0 \in [a, \infty)$  where  $F'(x_0) = f(x_0)$  if  $f$  is continuous at  $x_0$

*Proof.* Fix  $\epsilon$  and  $[a, b]$ . We only wish

to prove  $F$  is continuous on  $[a, b]$

To prove  $F$  is continuous on  $[a, b]$ , we only wish

to find  $\delta$  such that  $\forall [x, y] \subseteq [a, b], |x - y| < \delta \implies |F(x) - F(y)| < \epsilon$

Because  $f$  is proper-Riemann-Integrable on  $[a, b]$ , we know  $f$  is bounded on  $[a, b]$ . Let  $M$  be an upper bound of  $|f|$  on  $[a, b]$ . We claim

$$\delta = \frac{\epsilon}{M} \text{ works}$$

Because  $y - x < \delta = \frac{\epsilon}{M}$ , we have

$$\begin{aligned} |F(x) - F(y)| &= \left| \int_x^y f(t)dt \right| \\ &\leq \int_x^y |f(t)| dt \\ &\leq (y - x) < \epsilon \text{ (done)} \end{aligned}$$

Now, to prove  $F'(x_0) = f(x_0)$ , we wish

$$\text{to prove } \lim_{x \rightarrow x_0} \frac{F(x) - F(x_0)}{x - x_0} = f(x_0)$$

Fix  $\epsilon$ . We wish

$$\text{to find } \delta \text{ such that } |x - x_0| < \delta \implies \left| \frac{F(x) - F(x_0)}{x - x_0} - f(x_0) \right| < \epsilon$$

Because  $f$  is continuous at  $x_0$ , we know

$$\exists \delta, |x - x_0| < \delta \implies |f(x) - f(x_0)| < \epsilon \quad (3.38)$$

We claim

such  $\delta$  in Equation 3.38 works

WOLG, let  $x > x_0$ . Deduce

$$\begin{aligned} \left| \frac{F(x) - F(x_0)}{x - x_0} - f(x_0) \right| &= \left| \frac{\int_{x_0}^x f(t) dt}{x - x_0} - f(x_0) \right| \\ &= \left| \frac{\int_{x_0}^x [f(t) - f(x_0)] dt}{x - x_0} \right| \\ &\leq \frac{\int_{x_0}^x |f(t) - f(x_0)| dt}{|x - x_0|} \\ &\leq \frac{\int_{x_0}^x \epsilon dt}{|x - x_0|} = \epsilon \text{ (done)} \end{aligned}$$

■

**Theorem 3.7.2. (Fundamental Theorem of Calculus: Part 2, Leibniz Rule)** Suppose two functions  $f, F : [a, \infty) \rightarrow \mathbb{R}$  satisfy

- (a)  $f$  is proper Riemann-Integrable on  $[a, b]$  for all  $b > a$
- (b)  $F'(x) = f(x)$  for all  $x \in (a, \infty)$
- (c)  $F$  is continuous on  $[a, \infty)$

Then for all  $b > a$ ,

$$\int_a^b f(x) dx = F(b) - F(a)$$

*Proof.* Fix  $\epsilon$ . We wish

$$\text{to show that } \left| \left( F(b) - F(a) \right) - \int_a^b f(x) dx \right| < \epsilon$$

Because  $f$  is proper Riemann-Integrable on  $[a, b]$ , we know there exists a partition  $P = \{a = x_0, x_1, \dots, x_n = b\}$  of  $[a, b]$  such that

$$U(P, f) - L(P, f) < \epsilon \quad (3.39)$$

Because  $f = F'$  on  $(a, b)$ , for each  $k \in \{1, \dots, n\}$ , by MVT (Theorem 3.3.4), we know

$$\exists t_k \in (x_{k-1}, x_k), \frac{F(x_k) - F(x_{k-1})}{x_k - x_{k-1}} = f(t_k)$$

This let us deduce

$$F(b) - F(a) = \sum_{k=1}^n F(x_k) - F(x_{k-1}) = \sum_{k=1}^n f(t_k) \Delta x_k$$

Now, we have

$$\int_a^b f(x) dx \text{ and } F(b) - F(a) \text{ are both in } [L(P, f), U(P, f)]$$

Then by Equation 3.39, we can deduce

$$\left| F(b) - F(a) - \int_a^b f(x) dx \right| < \epsilon \text{ (done)}$$

■

**Theorem 3.7.3. (Integral By Part)** Given four function  $f, g, F, G : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $F'(x) = f(x)$  and  $G'(x) = g(x)$  for all  $x \in (a, b)$
- (b)  $f, g$  are properly Riemann-Integrable on  $[a, b]$
- (c)  $F, G$  are continuous on  $[a, b]$

We have

$$\int_a^b F(x)g(x)dx = FG \Big|_a^b - \int_a^b f(x)G(x)dx \quad (3.40)$$

*Proof.* To prove Equation 3.40, we only with

$$\text{to prove } \int_a^b F(x)g(x)dx + \int_a^b f(x)G(x)dx = FG \Big|_a^b$$

We can reduce the problem

into proving  $\int_a^b (Fg + fG)dx = FG \Big|_a^b$

Notice that by Chain Rule,

$$(FG)'(x) = F(x)g(x) + f(x)G(x) \text{ for all } x \in (a, b)$$

Then the result follows from Part 2 of Fundamental Theorem of Calculus (Theorem 3.7.2).  
(done) ■

### 3.8 Uniform Convergence on Integration and Differentiation

**Theorem 3.8.1. (Riemann-Integration and Uniform Convergence)** Given a function  $\alpha : [a, b] \rightarrow \mathbb{R}$  and a sequence of functions  $f_n : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $\alpha$  increase on  $[a, b]$
- (b)  $\int_a^b f_n d\alpha$  exists for all  $n \in \mathbb{N}$
- (c)  $f_n \rightarrow f$  uniformly on  $[a, b]$

Then

$$\lim_{n \rightarrow \infty} \int_a^b f_n d\alpha \text{ exists and } \int_a^b f d\alpha = \lim_{n \rightarrow \infty} \int_a^b f_n d\alpha$$

*Proof.* We first prove

$$\int_a^b f d\alpha \text{ exists}$$

Fix  $\epsilon$ . We wish to prove

$$\overline{\int_a^b f d\alpha} - \underline{\int_a^b f d\alpha} < \epsilon$$

Let  $\epsilon_n = \|f_n - f\|_\infty$ . Because  $f_n \rightarrow f$  uniformly, we know

$$\text{there exists } n \in \mathbb{N} \text{ such that } \epsilon_n = \|f_n - f\|_\infty < \frac{\epsilon}{2[\alpha(b) - \alpha(a)]}$$

Because  $\alpha$  increase, by definition of  $\epsilon_n$ , we see

$$\int_a^b (f_n - \epsilon_n) d\alpha \leq \underline{\int_a^b f d\alpha} \leq \overline{\int_a^b f d\alpha} \leq \int_a^b (f_n + \epsilon_n) d\alpha$$

Because  $\epsilon_n < \frac{\epsilon}{2[\alpha(b) - \alpha(a)]}$ , we now see

$$\begin{aligned} \overline{\int_a^b f d\alpha} - \underline{\int_a^b f d\alpha} &\leq \int_a^b (f_n + \epsilon_n) d\alpha - \int_a^b (f_n - \epsilon_n) d\alpha \\ &= \int_a^b (2\epsilon_n) d\alpha < 2\epsilon_n \cdot [\alpha(b) - \alpha(a)] = \epsilon \text{ (done)} \end{aligned}$$

We now prove

$$\int_a^b f_n d\alpha \rightarrow \int_a^b f d\alpha \text{ as } n \rightarrow \infty$$

Fix  $\epsilon$ . We wish

$$\text{to find } N \text{ such that } \forall n > N, \left| \int_a^b f_n d\alpha - \int_a^b f d\alpha \right| < \epsilon$$

Recall the definition  $\epsilon_n = \|f_n - f\|_\infty$ . Because  $\epsilon_n \rightarrow 0$ , we know

$$\text{there exists } N \text{ such that } \forall n > N, \epsilon_n < \frac{\epsilon}{\alpha(b) - \alpha(a)} \quad (3.41)$$

We claim

such  $N$  works

Fix  $n > N$ . From Equation 3.41, we see

$$\begin{aligned} \left| \int_a^b f_n d\alpha - \int_a^b f d\alpha \right| &= \left| \int_a^b (f_n - f) d\alpha \right| \\ &\leq \int_a^b |f_n - f| d\alpha \\ &\leq \int_a^b \epsilon_n d\alpha = \epsilon_n [\alpha(b) - \alpha(a)] < \epsilon \text{ (done)} \end{aligned}$$

■

Before the next Theorem, let's see three examples why this time we don't (can't) use the hypothesis:  $f_n \rightarrow f$  uniformly.

**Example 4 (Differentiable functions are NOT closed under uniform convergence)**

$$X = [-1, 1] \text{ and } f(x) = |x|$$

By Weierstrass approximation Theorem, there is a sequence of polynomials (differentiable) that uniformly converge to  $f$ , which is not differentiable at 0.

**Example 5 (Derivative won't necessarily converge to the right place)**

$$X = \mathbb{R} \text{ and } f_n(x) = \frac{\sin nx}{\sqrt{n}}$$

Compute

$$f'(x) = 0 \text{ and } f'_n(x) = \sqrt{n} \cos nx$$

**Example 6 (Derivative won't necessarily converge to the right place)**

$$X = \mathbb{R} \text{ and } f_n(x) = \frac{x}{1 + nx^2}$$

Compute

$$f = \tilde{0} \text{ and } f'_n(0) = 1$$

Informally speaking, these examples together with the fact integral are closed under uniform convergence (Theorem 3.8.1) should give you some ideas that differentiation and integration although are operations inverse to each other, are NOT symmetric. There is a certain hierarchy on continuous functions on a fixed compact interval. Thus, we have the next Theorem in its form. Note that in application, the next Theorem only require us to prove  $f'_n$  uniformly converge, and doesn't require us to prove to where does it converge.

**Theorem 3.8.2. (Uniform Convergence and Differentiation)** Given a sequence of function  $f_n : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $f'_n$  uniformly converge on  $(a, b)$
- (b)  $f_n$  are continuous on  $[a, b]$
- (c)  $f_n(x_0) \rightarrow L$  for some  $x_0 \in [a, b]$

Then

- (a)  $f_n$  uniformly converge on  $[a, b]$
- (b) and

$$\left( \lim_{n \rightarrow \infty} f_n \right)'(x_0) = \lim_{n \rightarrow \infty} f'_n(x_0) \text{ on } (a, b)$$

*Proof.* We first prove

$$f_n \text{ uniformly converge on } [a, b] \tag{3.42}$$

Fix  $\epsilon$ . We wish

to find  $N$  such that  $\|f_n - f_m\|_\infty \leq \epsilon$  for all  $n, m > N$

Because  $f_n(x_0)$  converge, and  $f'_n$  uniformly converge, we know there exists  $N$  such that

$$\begin{cases} |f_n(x_0) - f_m(x_0)| < \frac{\epsilon}{2} \\ \|f'_n - f'_m\|_\infty < \frac{\epsilon}{2(b-a)} \end{cases} \quad \text{for all } n, m > N \quad (3.43)$$

We claim

such  $N$  works

Fix  $x \in [a, b]$  and  $n, m > N$ . We need

to show  $|f_n(x) - f_m(x)| \leq \epsilon$

We first prove

$$|f_n(x) - f_m(x) - f_n(x_0) + f_m(x_0)| \leq \frac{\epsilon}{2}$$

Because  $(f_n - f_m)' = f'_n - f'_m$ , by MVT (Theorem 3.3.4) and Equation 3.43, we can deduce

$$\begin{aligned} |f_n(x) - f_m(x) - f_n(x_0) + f_m(x_0)| &= |(f_n - f_m)(x) - (f_n - f_m)(x_0)| \\ &= \left| [(f_n - f_m)'(t)](x - x_0) \right| \text{ for some } t \text{ between } x, x_0 \\ &< \frac{\epsilon}{2(b-a)} \cdot |x - x_0| \\ &\leq \frac{\epsilon}{2(b-a)} \cdot (b-a) = \frac{\epsilon}{2} \quad (\because x, x_0 \in [a, b]) \quad (\text{done}) \end{aligned}$$

Now, by Equation 3.43, we have

$$\begin{aligned} |f_n(x) - f_m(x)| &\leq |f_n(x) - f_m(x) - f_n(x_0) + f_m(x_0)| + |f_n(x_0) - f_m(x_0)| \\ &< \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \quad (\text{done}) \end{aligned}$$

We claim

$$f(x) \triangleq \lim_{n \rightarrow \infty} f_n(x) \text{ satisfy } f'(x) = \lim_{n \rightarrow \infty} f'_n(x) \text{ on } (a, b) \quad (3.44)$$

We first show

$f$  is differentiable on  $(a, b)$

Fix  $x \in (a, b)$ . We wish to prove

$$\lim_{t \rightarrow x} \frac{f(t) - f(x)}{t - x} \text{ exists}$$

Define  $\phi : [a, b] \setminus x \rightarrow \mathbb{R}$  by

$$\phi(t) \triangleq \frac{f(t) - f(x)}{t - x}$$

We reduce our problem into proving

$$\lim_{t \rightarrow x} \phi(t) \text{ exists}$$

Set  $\phi_n : [a, b] \setminus x \rightarrow \mathbb{R}$  by

$$\phi_n(t) \triangleq \frac{f_n(t) - f_n(x)}{t - x}$$

We first show

$$\phi_n \text{ uniformly converge on } [a, b] \setminus x \quad (3.45)$$

Fix  $\epsilon$ . We have

$$\text{to find } N \text{ such that } |\phi_n(t) - \phi_m(t)| \leq \epsilon \text{ for all } n, m > N \text{ and } t \in [a, b] \setminus x$$

Because  $f'_n$  uniformly converge on  $[a, b]$ , we know there exists  $N$  such that

$$\|f'_n - f'_m\|_\infty \leq \epsilon \text{ for all } n, m > N \quad (3.46)$$

We claim

$$\text{such } N \text{ works}$$

Fix  $n, m > N$  and  $t \in [a, b] \setminus x$ . We wish to prove

$$|\phi_n(t) - \phi_m(t)| \leq \epsilon$$

Because  $(f_n - f_m)' = f'_n - f'_m$ , by MVT (Theorem 3.3.4) and Equation 3.46, we can deduce

$$\begin{aligned} |\phi_n(t) - \phi_m(t)| &\leq \left| \frac{f_n(t) - f_n(x)}{t - x} - \frac{f_m(t) - f_m(x)}{t - x} \right| \\ &= \left| \frac{(f_n - f_m)(t) - (f_n - f_m)(x)}{t - x} \right| \\ &= |(f'_n - f'_m)(t_0)| \text{ for some } t_0 \text{ between } t, x \\ &\leq \epsilon \text{ (done)} \end{aligned}$$

We now show

$$\phi_n \rightarrow \phi \text{ pointwise on } [a, b] \setminus x \quad (3.47)$$

Because  $f_n \rightarrow f$  on  $[a, b]$  by definition (Equation 3.44), (the convergence is in fact uniform as we have shown. This doesn't matter here tho), for each  $t \in [a, b] \setminus x$ , we can deduce

$$\lim_{n \rightarrow \infty} \phi_n(t) = \lim_{n \rightarrow \infty} \frac{f_n(t) - f_n(x)}{t - x} = \frac{f(t) - f(x)}{t - x} = \phi(t) \text{ (done)}$$

Now, by Equation 3.45 and Equation 3.47, we know

$$\phi_n \rightarrow \phi \text{ uniformly on } [a, b] \setminus x$$

Notice that because  $f'_n(x)$  converge, we know

$$\lim_{n \rightarrow \infty} \lim_{t \rightarrow x} \phi_n(t) = \lim_{n \rightarrow \infty} f'_n(x) \text{ exists}$$

Then (Notice that the second equality below hold true because we have known  $\lim_{n \rightarrow \infty} \lim_{t \rightarrow x} \phi_n(t)$  exists), we can finally deduce

$$\begin{aligned} \lim_{t \rightarrow x} \phi(t) &= \lim_{t \rightarrow x} \lim_{n \rightarrow \infty} \phi_n(t) \\ &= \lim_{n \rightarrow \infty} \lim_{t \rightarrow x} \phi_n(t) \\ &= \lim_{n \rightarrow \infty} f'_n(x) \text{ exists (done)} \end{aligned}$$

Now, notice that  $f'(x) = \lim_{t \rightarrow x} \phi(t)$ , so in fact, we have just proved  $f'_n \rightarrow f'$  (done) (done) ■

As Rudin remarked, a much shorter (and much more intuitive) proof can be given, if we require  $f'$  to be continuous on  $[a, b]$ .

**Theorem 3.8.3. (Uniform Convergence and Differentiation: Weaker Version)**

Given a sequence of function  $f_n : [a, b] \rightarrow \mathbb{R}$  such that

- (a)  $f'_n$  uniformly converge on  $[a, b]$
- (b)  $f_n(x_0) \rightarrow L$  for some  $x_0 \in [a, b]$
- (c)  $f_n$  are of class  $C^1$  on  $[a, b]$

Then

- (a)  $f_n$  uniformly converge on  $[a, b]$

(b) and

$$\frac{d}{dx} \left( \lim_{n \rightarrow \infty} f_n(x) \right) \Big|_{x=x_0} = \lim_{n \rightarrow \infty} f'_n(x_0) \text{ on } (a, b)$$

*Proof.* We claim

$$f(x) = \lim_{n \rightarrow \infty} \int_{x_0}^x f'_n(t) dt + L \text{ works}$$

Note that  $\lim_{n \rightarrow \infty} \int_{x_0}^x f'_n(t) dt$  exists because  $f'_n$  uniformly converge (Theorem 3.8.1).

Because  $f'_n$  uniformly converge and are continuous on  $[a, b]$ , by ULT, we know

$$\int_{x_0}^x \lim_{n \rightarrow \infty} f'_n(t) dt + L \text{ exists}$$

and know

$$f(x) = \int_{x_0}^x \lim_{n \rightarrow \infty} f'_n(t) dt + L$$

By FTC, we see

$$f'(x) = \lim_{n \rightarrow \infty} f'_n(x) \text{ on } (a, b)$$

Such convergence is uniform by premise. To finish the proof, we now only have to prove

$$f_n \rightarrow f \text{ uniformly on } [a, b]$$

Fix  $\epsilon$ . We wish

$$\text{to find } N \text{ such that } |f_n(x) - f(x)| \leq \epsilon \text{ for all } n > N \text{ and } x \in [a, b]$$

Because  $f'_n \rightarrow f'$  uniformly, and  $f_n(x_0) \rightarrow L = f(x_0)$  (Check  $L = f(x_0)$ ), we know there exists  $N$  such that

$$\begin{cases} \|f'_n - f'\|_\infty < \frac{\epsilon}{2(b-a)} \\ |f_n(x_0) - f(x_0)| < \frac{\epsilon}{2} \end{cases} \quad \text{for all } n > N$$

We claim

$$\text{such } N \text{ works}$$

Fix  $n > N$  and  $x \in [a, b]$ . Observe

$$\begin{aligned} |f(x) - f_n(x)| &= \left| \int_{x_0}^x (f'(t) - f'_n(t)) dt + f(x_0) - f_n(x_0) \right| \\ &\leq \int_{x_0}^x |f'(t) - f'_n(t)| dt + |f(x_0) - f_n(x_0)| \\ &\leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \text{ (done)} \end{aligned}$$

**Theorem 3.9.17. (Special Sequence)**  $(n!)^{\frac{1}{n}}$

## 3.10 Analytic Functions

In this section, by a **real power series**, we mean a pair  $(a, c_n)$  where  $a \in \mathbb{R}$  is called the **center** of power series, and  $c_n \in \mathbb{R}$  are the coefficients sequence. By **radius of convergence**, we mean a unique  $R \in \mathbb{R}_0^+ \cup \infty$  such that

$$\sum_{n=0}^{\infty} c_n(x-a)^n \begin{cases} \text{converge absolutely} & \text{if } |x-a| < R \\ \text{diverge} & \text{if } |x-a| > R \end{cases}$$

Such  $R$  always exist (and is unique, this fact can be checked without computing the actual value of  $R$ ) and is exactly

$$R = \frac{1}{\limsup_{n \rightarrow \infty} \sqrt[n]{c_n}} \quad (3.48)$$

This result is called **Cauchy-Hadamard Theorem**. It can be directly proved by applying Root Test to  $\sum c_n(z-a)^n$ . For this, we say  $(a-R, a+R)$  is the **interval of convergence**. Note that Cauchy-Hadamard Theorem does not tell us whether a power series converges at points of boundary of disk of convergence. It require extra works to determine if the power series converge at endpoints. Following is an example of such discussion.

### Example 7 (Discussion of Convergence on Boundary)

$$f_q(z) = \sum_{n=0}^{\infty} n^q z^n \text{ provided } q \in \mathbb{R}$$

It is clear that  $f_q$  has convergence radius 1 for all  $q \in \mathbb{R}$ . For boundary, we have

$$\begin{cases} q < -1 \implies f_q \text{ converge on } S^1 \\ -1 \leq q < 0 \implies f_q \text{ converge on } S^1 \setminus \{1\} \\ 0 \leq q \implies f_q \text{ diverge on } S^1 \end{cases}$$

At  $z = 1$ , the discussion is just p-series. On  $S^1 \setminus \{1\}$ , the discussion use Dirichlet's Test, where boundedness of  $\sum_{k=0}^n z^k$  is proved by geometric formula.

$$\left| \sum_{k=1}^n z^k \right| = \left| \sum_{k=1}^n e^{ik\theta} \right| = \frac{|e^{i\theta} - e^{i(n+1)\theta}|}{|1 - e^{i\theta}|} \leq \frac{2}{|1 - e^{i\theta}|}$$

Notice that the fact  $\sum c_n(z-a)^n$  absolutely converge in  $(a-R, a+R)$  implies the convergence is uniform on all  $[a-R+\epsilon, a+R-\epsilon]$  by M-Test. However, on  $(a-R, a+R)$ , the convergence is not always uniform.

**Example 8 (Failure of Uniform Convergence on  $(a-R, a+R)$ )**

$$f(z) = \sum_{n=0}^{\infty} z^n$$

Note  $R = 1$ . Use Geometric Series Formula to show  $f(x) = \frac{1}{1-x}$  on  $(-1, 1)$ . It is then clear that  $f$  is unbounded on  $(-1, 1)$  while all partial sums  $\sum_{k=0}^n z^k$  is bounded on  $(-1, 1)$ .

We now introduce some terminologies. We say a real function  $f$  is **real analytic at**  $a \in \mathbb{R}$  if there exists a power series  $(a, c_n)$  such that  $f$  agrees with  $\sum_{n=0}^{\infty} c_n(z-a)^n$  on  $(a-R, a+R)$  for some  $R$  (of course, such  $R$  must not be strictly greater than the radius of convergence of  $(a, c_n)$ ).

It shall be quite clear that if  $f, g$  are both analytic at  $a \in \mathbb{R}$  with radius  $R_f \leq R_g$ , then  $f+g$  and  $fg$  are both analytic at  $a$  with radius at least  $R_f$ . (the fact  $fg$  is analytic at  $a$  with radius at least  $R_f$  is an immediate consequence of Merten's Theorem)

We now investigate deeper into real analytic functions. We first prove that real analytic functions are smooth, that is,  $C^\omega(I) \subseteq C^\infty(I)$  on open  $I \subseteq \mathbb{R}$ .

**Theorem 3.10.1. (Analytic functions are Smooth)** Given a power series  $(a, c_n)$  of convergence radius  $R$ , if we define  $f : D_R(a) \rightarrow \mathbb{C}$  by

$$f(z) = \sum_{n=0}^{\infty} c_n(z-a)^n$$

Then

- (a)  $f$  is of class  $C^\infty$  on  $D_R(a)$
- (b)  $f^{(k)}(z) = \sum_{n=k}^{\infty} \frac{n!}{(n-k)!} c_n(z-a)^{n-k}$

*Proof.* We prove by induction. Base case  $k = 0$  is trivial. Fix  $k \geq 0$ . Suppose we have

$$f^{(k)}(z) = \sum_{n=k}^{\infty} \frac{n!}{(n-k)!} c_n(z-a)^{n-k} \text{ on } D_R(a)$$

We are required to prove

$$f^{(k+1)}(z) = \sum_{n=k+1}^{\infty} \frac{n!}{(n-k-1)!} c_n (z-a)^{n-k-1} \text{ on } D_R(a)$$

Set  $f_m$

$$f_m(z) \triangleq \sum_{n=k}^{k+m} \frac{n!}{(n-k)!} c_n (z-a)^{n-k}$$

We have

$$f_m \rightarrow f^{(k)} \text{ pointwise on } D_R(a) \text{ and } f'_m(z) = \sum_{n=k+1}^{k+m} \frac{n!}{(n-k-1)!} c_n (z-a)^{n-k-1} \quad (3.49)$$

We abstract our problem into proving

$$f'_m \rightarrow f^{(k+1)} \text{ pointwise on } D_R(a)$$

Fix  $z_0 \in D_R(a)$ . We only wish to prove

$$(f^{(k)})'(z_0) = \lim_{m \rightarrow \infty} f'_m(z_0)$$

Fix  $\epsilon$  such that  $|z_0 - a| < R - \epsilon$ . By Equation 3.49, using Theorem 3.8.2 (Uniform Convergence and Differentiation). We only have to prove

$$f'_m \text{ uniformly converge on } \overline{D}_{R-\epsilon}$$

Note that

$$f'_m(z) = \sum_{n=0}^{m-1} \frac{(n+k+1)!}{n!} c_{n+k+1} (z-a)^n$$

so we can compute the radius of convergence for  $f'_m$

$$\begin{aligned} \limsup_{n \rightarrow \infty} \sqrt[n]{\frac{(n+k+1)!}{n!} |c_{n+k+1}|} &= \limsup_{n \rightarrow \infty} \sqrt[n]{|c_{n+k+1}|} \\ &= \limsup_{n \rightarrow \infty} \sqrt[n]{|c_n|} = R \end{aligned}$$

Together by Cauchy-Hadamard (absolute convergent on  $a + R - \epsilon$ ) and M-test show that

$$\sum_{n=0}^{\infty} \frac{(n+k+1)!}{n!} c_{n+k+1} (z-a)^n \text{ uniformly converge on } \overline{D}_{R-\epsilon}(a) \quad (\text{done})$$

■

Now by Theorem 3.10.1, if we are given a real function  $f$  analytic at  $a$ , the power series representation  $(a, c_n) : \sum_{n=0}^{\infty} c_n(z - a)^n = f$  must be unique, since  $f$  is proved to be infinitely differentiable at  $a$  and proved to satisfy  $c_k = \frac{f^{(k)}(a)}{k!}$ .

Notice that the arguments above are all based on the hypothesis that  $f$  is analytic, and that smoothness does not imply analytic. See the following examples.

### Example 9 (Smooth but not Analytic Function)

$$f(x) = \begin{cases} e^{-\frac{1}{x^2}} & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

Use induction to show that

$$f^{(k)}(x) = P_k\left(\frac{1}{x}\right)e^{-\left(\frac{1}{x}\right)^2} \quad \exists P_k \in \mathbb{R}[x^{-1}], \forall k \in \mathbb{Z}_0^+, \forall x \in \mathbb{R}^*$$

and again use induction to show that

$$f^{(k)}(0) = 0 \quad \forall k \in \mathbb{Z}_0^+$$

The trick to show  $f^{(k)}(0) = 0$  is let  $u = \frac{1}{x}$ .

Now, with Theorem 3.10.1, we see that  $f$  is not analytic at 0.

### Example 10 (Bump Function)

$$f(x) = \begin{cases} e^{-\frac{1}{1-x^2}} & \text{if } |x| < 1 \\ 0 & \text{otherwise} \end{cases}$$

Use the same trick (but more advanced) to show  $f$  is smooth, and note that  $f$  is not analytic at  $\pm 1$ .

Now, it comes an interesting question. Given a real function  $f$  analytic at  $a$  with radius  $R$ , and suppose  $b \in (a - R, a + R)$ .

- (a) Is  $f$  also analytic at  $b$ ?
- (b) What do we know about the radius of convergence of  $f$  at  $b$ ?

(c) Suppose  $f$  is indeed analytic at  $b$ . It is trivial to see that the power series  $(a, c_{a;n})$  and  $(b, c_{b;n})$  must agree on the common convergence interval, and because  $f$  is given, we by Theorem 3.10.1, have already known the value of  $c_{b;n}$ . Can we verify that the power series  $(a, c_{a;n})$  and  $(a, c_{b;n})$  do indeed agree with each other on the common convergence interval?

Theorem 3.10.2 (Taylor's Theorem) give satisfying answers to these problems.

**Theorem 3.10.2. (Taylor's Theorem)** Given a real function  $f$  analytic at  $a$  with radius  $R$ , and suppose  $b \in (a - R, a + R)$ . Then

$$f(x) = \sum_{k=0}^{\infty} \frac{f^{(k)}(b)}{k!} (x - b)^k \text{ on } |x - b| < R - |b - a|$$

*Proof.* WOLG, let  $a = 0$ . Suppose  $x$  satisfy  $|x - b| < R - |b|$ . Compute

$$\begin{aligned} f(x) &= \sum_{k=0}^{\infty} \frac{f^{(k)}(a)}{k!} x^k \\ &= \sum_{k=0}^{\infty} \frac{f^{(k)}(a)}{k!} (x - b + b)^k \\ &= \sum_{k=0}^{\infty} \frac{f^{(k)}(a)}{k!} \sum_{n=0}^k \binom{k}{n} (x - b)^n b^{k-n} \\ &= \sum_{k=0}^{\infty} \sum_{n=0}^k \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x - b)^n b^{k-n} \end{aligned}$$

Note that

$$\begin{aligned} \sum_{k=0}^{\infty} \left| \sum_{n=0}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x - b)^n b^{k-n} \right| &\leq \sum_{k=0}^{\infty} \sum_{n=0}^{\infty} \left| \frac{f^{(k)}(a)}{k!} \right| \binom{k}{n} |x - b|^n \cdot |b|^{k-n} \\ &= \sum_{k=0}^{\infty} \left| \frac{f^{(k)}(a)}{k!} \right| \sum_{n=0}^{\infty} \binom{k}{n} |x - b|^n \cdot |b|^{k-n} \\ &= \sum_{k=0}^{\infty} \left| \frac{f^{(k)}(a)}{k!} \right| (|x - b| + |b|)^k \end{aligned}$$

converge, by Cauchy-Hadamard Theorem and  $|x - b| + |b| < R$ .

Now, using Fubini's Theorem for Infinite Series, we have

$$\begin{aligned}
\sum_{k=0}^{\infty} \sum_{n=0}^k \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x-b)^n b^{k-n} &= \sum_{k=0}^{\infty} \sum_{n=0}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x-b)^n b^{k-n} \\
&= \sum_{n=0}^{\infty} \sum_{k=0}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x-b)^n b^{k-n} \\
&= \sum_{n=0}^{\infty} \sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} (x-b)^n b^{k-n} \\
&= \sum_{n=0}^{\infty} \left[ \sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} b^{k-n} \right] (x-b)^n
\end{aligned}$$

We have reduced the problem into proving

$$\sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} b^{k-n} = \frac{f^{(n)}(b)}{n!}$$

Using the formula in Theorem 3.10.1, because  $b$  is in  $(a-R, a+R)$ , we can compute

$$\begin{aligned}
f^{(n)}(b) &= \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} c_{a;k}(b)^{k-n} \\
&= \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} \cdot \frac{f^{(k)}(a)}{k!} \cdot b^{k-n} \\
&= \sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{(k-n)!} b^{k-n}
\end{aligned}$$

This now implies

$$\begin{aligned}
\frac{f^{(n)}(b)}{n!} &= \sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{n!(k-n)!} b^{k-n} \\
&= \sum_{k=n}^{\infty} \frac{f^{(k)}(a)}{k!} \binom{k}{n} b^{k-n} \text{ (done)}
\end{aligned}$$

■

## Chapter 4

# Calculus in Euclidean Space

### 4.1 Operator Norm

---

## 4.2 Differentiability Theorem

Given two normed space  $V, W$ , suppose  $f$  maps an open neighborhood  $O$  around  $x$  in  $V$  to  $W$ . We say  $f$  is **differentiable at  $x$**  if there exists a linear transformation  $A_x : V \rightarrow W$  (from now,  $A_x$  will be denoted  $df_x$ ) such that the remainder of the local approximation  $df_x$  satisfy

$$\lim_{h \rightarrow 0} \frac{\|f(x+h) - f(x) - df_x(h)\|_W}{\|h\|_V} = 0$$

Given a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  and a normal vector  $e_i \in \mathbb{R}^n$ , the **partial derivative**  $\partial_i f : \mathbb{R}^n \rightarrow \mathbb{R}$  is defined by

$$\partial_i f(x) = \lim_{t \rightarrow 0} \frac{f(x + te_i) - f(x)}{t}$$

Given a function  $f : E \rightarrow \mathbb{R}^m$  and an orthonormal basis  $\{e_\lambda\}$  of  $\mathbb{R}^n$ , we use  $f_j$  to denote  $f \cdot e_j$ .

**Theorem 4.2.1. (Derivative is Jacobian)** Suppose  $\alpha = \{e_1, \dots, e_n\}$  is an orthonormal basis of  $\mathbb{R}^n$ , and  $\beta = \{q_1, \dots, q_m\}$  is an orthonormal basis of  $\mathbb{R}^m$ . Suppose  $f$  maps an open neighborhood  $O$  around  $x \in \mathbb{R}^n$  to  $\mathbb{R}^m$ . Then

$$f \text{ is differentiable at } x \implies \begin{cases} \partial_i f_j(x) \text{ exists for all } i, j \\ [df_x]_\alpha^\beta = \begin{bmatrix} \partial_1 f_1(x) & \cdots & \partial_n f_1(x) \\ \vdots & \ddots & \vdots \\ \partial_1 f_m(x) & \cdots & \partial_n f_m(x) \end{bmatrix} \end{cases}$$

*Proof.* Fix  $i, j$ . We wish to show

$$\lim_{t \rightarrow 0} \frac{f_j(x + te_i) - f_j(x)}{t} \text{ exists}$$

Because  $f$  is differentiable at  $x$ , by definition of  $df_x$ , we have

$$\lim_{t \rightarrow 0} \frac{|f(x + te_i) - f(x) - df_x(te_i)|}{|te_i|} = 0$$

Set  $R_i : \mathbb{R} \rightarrow \mathbb{R}^m$  by  $R_i(t) \triangleq f(x + te_i) - f(x) - df_x(te_i)$ . We have

$$\lim_{t \rightarrow 0} \frac{|R_i(t)|}{|t|} = 0 \tag{4.1}$$

Compute

$$\begin{aligned} f_j(x + te_i) - f_j(x) &= (f(x + te_i) - f(x)) \cdot q_j \\ &= (R_i(t) + df_x(te_i)) \cdot q_j \\ &= R_i(t) \cdot q_j + t df_x(e_i) \cdot q_j \end{aligned}$$

This then give us

$$\frac{f_j(x + te_i) - f_j(x)}{t} = \frac{R_i(t) \cdot q_j}{t} + df_x(e_i) \cdot q_j$$

and

$$df_x(e_i) \cdot q_j - \frac{|R_i(t) \cdot q_j|}{|t|} \leq \frac{f_j(x + te_i) - f_j(x)}{t} \leq df_x(e_i) \cdot q_j + \frac{|R_i(t) \cdot q_j|}{|t|}$$

By Cauchy-Schwarz Inequality, we now have

$$df_x(e_i) \cdot q_j - \frac{|R_i(t)|}{|t|} \leq \frac{f_j(x + te_i) - f_j(x)}{t} \leq df_x(e_i) \cdot q_j + \frac{|R_i(t)|}{|t|}$$

Now applying Squeeze Theorem and Equation 4.1, we have

$$\lim_{t \rightarrow 0} \frac{f_j(x + te_i) - f_j(x)}{t} = df_x(e_i) \cdot q_j \text{ (done)}$$

We now have

$$df_x(e_i) \cdot q_j = \partial_i f_j(x) \quad (\forall i, j)$$

This now give us

$$df_x(e_i) = \sum_{j=1}^m \left( df_x(e_i) \cdot q_j \right) q_j = \sum_{j=1}^m \partial_i f_j(x) q_j$$

and suggest the matrix representation. ■

Note that the converse is not always true, that is, given  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$ , even if the partial derivative  $\partial_i f_j$  all exists at  $x$ , the function  $f$  can still not be differentiable at  $x$ . In fact, it doesn't even have to be continuous at  $x$ . See the following examples.

**Example 11 (Discontinuous Function with Partial Derivative)**

$$f : \mathbb{R}^2 \rightarrow \mathbb{R} \text{ and } f(x, y) = \begin{cases} 1 & \text{otherwise} \\ 0 & \text{if } x = 0 \text{ or } y = 0 \end{cases}$$

**Example 12 (Discontinuous Function with Partial Derivative)**

$$f : \mathbb{R}^2 \rightarrow \mathbb{R} \text{ and } f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^2} & \text{if } (x, y) \neq 0 \\ 0 & \text{if } (x, y) = 0 \end{cases}$$

We have

$$f(h, h^2) \rightarrow \frac{1}{2} \text{ as } h \rightarrow 0 \text{ and } \partial_x f(0) = \partial_y f(0) = 0$$

**Example 13 (Non-differentiable Continuous Function with Partial Derivative)**

$$f : \mathbb{R}^2 \rightarrow \mathbb{R} \text{ and } f(x, y) = \begin{cases} \frac{x|y|}{\sqrt{x^2 + y^2}} & \text{if } (x, y) \neq 0 \\ 0 & \text{if } (x, y) = 0 \end{cases}$$

We have

$$\partial_x f(0) = \partial_y f(0) = 0$$

By Theorem 4.2.1 (Derivative is Jacobian), if  $f$  is differentiable at 0, then  $df_0$  must be trivial. Yet

$$\frac{|f(h, h) - f(0) - df_0(h, h)|}{|(h, h)|} = \frac{|h| \sqrt{2}}{|h| \sqrt{2}} \rightarrow 1$$

Note that  $f$  is continuous at 0, by observing

$$x^2 + y^2 - 2|xy| = (|x| - |y|)^2 \geq 0 \implies \frac{x^2 + y^2}{2} \geq |xy|$$

which implies

$$|f| \leq \frac{\sqrt{x^2 + y^2}}{2}$$

On the space  $L(V, W)$  of linear transformations from  $V$  to  $W$ , we can define a norm by

$$\|A\| = \sup_{\|x\|_V \leq 1} \|Ax\|_W$$

Check that this norm on  $L(V, W)$  indeed satisfy the axioms.

We say  $f : E \subseteq V \rightarrow W$  is **continuously differentiable** at limit point  $y \in E$  if

$$x \mapsto df_x \text{ is continuous at } y$$

Note that the definition coincide when  $V = W = \mathbb{R}$  and  $df_x$  is just  $h \mapsto f'(x)h$ .

**Theorem 4.2.2. (Differentiability Theorem)** Suppose  $\alpha = \{e_1, \dots, e_n\}$  is an orthonormal basis of  $\mathbb{R}^n$ , and  $\beta = \{q_1, \dots, q_m\}$  is an orthonormal basis of  $\mathbb{R}^m$ . Suppose  $f$  maps an open set  $O \subseteq \mathbb{R}^n$  to  $\mathbb{R}^m$ . Then

$f$  is continuously differentiable on  $O \iff \partial_i f_j$  exists and is continuous on  $O$  for all  $i, j$

## 4.3 Inverse Function Theorem

**Theorem 4.3.1. (Inverse Function Theorem)** Given a map  $f$  from open set  $E \subseteq \mathbb{R}^n$  to  $\mathbb{R}^n$  such that

- (a)  $f$  is continuously differentiable on  $E$
- (b)  $df_a$  is invertible
- (c)  $f(a) = b$

Then there exists open neighborhood  $U$  around  $a$  and  $V$  around  $b$  such that

$f$  is a diffeomorphism from  $U$  to  $V$

## 4.4 Implicit Function Theorem

## 4.5 Linear Algebra Review

This section give an

(a)

### (Norm Axiom Part)

Recall that by a **normed space**  $V$ , we mean a vector space over a sub-field  $\mathbb{F}$  of  $\mathbb{C}$  equipped with  $\|\cdot\| : V \rightarrow \mathbb{R}_0^+$  satisfying the following axioms:

- (a)  $\|x\| = 0 \implies x = 0$  (positive-definiteness)
- (b)  $\|sx\| = |s| \cdot \|x\|$  for all  $s \in \mathbb{F}$  and  $x \in V$  (absolute-homogeneity)
- (c)  $\|x + y\| \leq \|x\| + \|y\|$  for all  $x, y \in V$  (triangle inequality)

Observe

$$\|0\| = \|0 + x\| \leq \|0\| + \|x\| \text{ for all } x \in V$$

This shows that  $\|x\| \geq 0$  for all  $x \in V$ . Also observe

$$\|0\| = \|0(x)\| = |0| \cdot \|x\| = 0$$

We can now rewrite the normed space axioms into

- (a)  $\|x\| = 0 \iff x = 0$  (positive-definiteness)
- (b)  $\|sx\| = |s| \cdot \|x\|$  for all  $s \in \mathbb{F}$  and  $x \in V$  (absolute-homogeneity)
- (c)  $\|x + y\| \leq \|x\| + \|y\|$  for all  $x, y \in V$  (triangle inequality)
- (d)  $\|x\| \geq 0$  for all  $x \in V$  (non-negativity)

### (Inner Product Axiom Part)

Recall that by an **inner product space**  $V$ , we mean a vector space over  $\mathbb{R}$  or  $\mathbb{C}$  equipped with  $\langle \cdot, \cdot \rangle : V^2 \rightarrow \mathbb{R}$  or  $\mathbb{C}$  satisfying the following axioms

- (a)  $\langle x, x \rangle > 0$  for all  $x \neq 0$  (Positive-definiteness)
- (b)  $\langle x, y \rangle = \overline{\langle y, x \rangle}$  (Conjugate symmetry)
- (c)  $\langle x + y, z \rangle = \langle x, z \rangle + \langle y, z \rangle$  and  $\langle cx, z \rangle = c\langle x, z \rangle$  (Linearity in the first argument)

Note that conjugate symmetry let us deduce

$$\langle x, x \rangle = \overline{\langle x, x \rangle} \implies \langle x, x \rangle \in \mathbb{R}$$

Also, one can easily use linearity in first argument to deduce

$$\langle 0, 0 \rangle = 2\langle 0, 0 \rangle \implies \langle 0, 0 \rangle = 0$$

This now let us rewrite the inner product space over  $\mathbb{C}$  axioms into

- (a)  $\langle x, x \rangle \geq 0$  for all  $x \in V$  (non-negativity)
- (b)  $\langle x, x \rangle = 0 \iff x = 0$  (positive-definiteness)
- (c)  $\langle x, y \rangle = \overline{\langle y, x \rangle}$  (conjugate symmetry)
- (d)  $\langle cx + y, z \rangle = c\langle x, z \rangle + \langle y, z \rangle$  and  $\langle x, cy + z \rangle = \bar{c}\langle x, y \rangle + \langle x, z \rangle$  (Linearity)

Note that using  $c = 1$  and  $y = 0$ , ( $\because \langle 0, z \rangle = 0 \langle x, z \rangle = 0$ ) one can check that the latter expression of linearity implies the first expression.

If the scalar field is  $\mathbb{R}$ , then conjugate symmetry is just symmetry and we also have linearity in the second argument.

This now let us rewrite the inner product space over  $\mathbb{R}$  axioms into

- (a)  $\langle x, x \rangle \geq 0$  for all  $x \in V$  (non-negativity)
- (b)  $\langle x, x \rangle = 0 \iff x = 0$  (positive-definiteness)
- (c)  $\langle x, y \rangle = \langle y, x \rangle$  (symmetry)
- (d) Linearity in both arguments

If we do not require  $\langle \cdot, \cdot \rangle$  to be positive-definite, but only non-negative, i.e.  $\langle x, x \rangle \geq 0$  for all  $x \in V$ , then we have a **positive semi-definite Hermitian form**. Formally speaking, a positive semi-definite Hermitian form  $\langle \cdot, \cdot \rangle : V^2 \rightarrow \mathbb{R}$  or  $\mathbb{C}$  satisfy the following axioms

- (a)  $\langle x, x \rangle \geq 0$  for all  $x \in V$  (non-negativity)
- (b)  $\langle x, y \rangle = \overline{\langle y, x \rangle}$  (conjugate symmetry)
- (c)  $\langle x + y, z \rangle = \langle x, z \rangle + \langle y, z \rangle$  and  $\langle cx, z \rangle = c\langle x, z \rangle$  (Linearity in the first argument)

**Example 14 (Example of Positive semi-definite Hermitian form)**

arbitrary  $V$  over  $\mathbb{R}$  or  $\mathbb{C}$      $\langle x, y \rangle \triangleq 0$  for all  $x, y$

**(Norm Induce Part)**

Given a vector space  $V$  over  $\mathbb{R}$  or  $\mathbb{C}$ , one can check that if  $V$  is equipped with an inner product  $\langle \cdot, \cdot \rangle : V^2 \rightarrow \mathbb{R}$  or  $\mathbb{C}$ , then we can induce a norm on  $V$  by

$$\|x\| \triangleq \sqrt{\langle x, x \rangle} \quad (x \in V)$$

Note that

$$\|x\| = 0 \iff \langle x, x \rangle = 0$$

This implies that if  $\langle \cdot, \cdot \rangle$  is an inner product (satisfy positive-definiteness), then  $\|\cdot\|$  is also positive-definite. And if  $\langle \cdot, \cdot \rangle$  is not positive-definite, then there exists  $x \neq 0 \in V$  such that  $\|x\| = 0$ , which make  $\|\cdot\|$  a **semi-norm**.

Absolute homogeneity follows from the linearity of inner product.

To check triangle inequality, we first have to prove Cauchy-Schwarz inequality.

**Theorem 4.5.1. (Basic Property of Positive semi-definite Hermitian form)** Given a positive semi-definite Hermitian form  $\langle \cdot, \cdot \rangle : V^2 \rightarrow \mathbb{R}$  or  $\mathbb{C}$  and  $x, y \in V$ , we have

$$\langle x, x \rangle = 0 \implies \langle x, y \rangle = 0$$

*Proof.* Assume  $\langle x, y \rangle \neq 0$ . Fix  $t > \frac{\|y\|^2}{2|\langle x, y \rangle|^2}$ . Compute

$$\begin{aligned} \|y - t\langle y, x \rangle x\|^2 &= \|y\|^2 + \|(-t)\langle y, x \rangle x\|^2 + \langle -t\langle y, x \rangle x, y \rangle + \langle y, -t\langle y, x \rangle x \rangle \\ &= \|y\|^2 + t^2 |\langle x, y \rangle|^2 \|x\|^2 - t\langle y, x \rangle \langle x, y \rangle - t\langle x, y \rangle \langle y, x \rangle \\ &= \|y\|^2 - 2t |\langle x, y \rangle|^2 < 0 \quad \text{CaC} \end{aligned}$$

■

**Theorem 4.5.2. (Cauchy-Schwarz Inequality)** Given a positive semi-definite Hermitian form  $\langle \cdot, \cdot \rangle : V^2 \rightarrow \mathbb{C}$  on vector space  $V$  over  $\mathbb{C}$ , we have

(a)  $|\langle x, y \rangle| \leq \|x\| \cdot \|y\| \quad (x, y \in V)$

(b) the equality hold true if  $x, y$  are linearly dependent

(c) the equality hold true if and only if  $x, y$  are linearly dependent (provided  $\langle \cdot, \cdot \rangle$  is an inner product)

*Proof.* We first prove

$$|\langle x, y \rangle| \leq \|x\| \cdot \|y\| \quad (x, y \in V)$$

Fix  $x, y \in V$ . Theorem 4.5.1 tell us  $\|x\| = 0 \implies \langle x, y \rangle = 0$ . Then we can reduce the problem into proving

$$\frac{|\langle x, y \rangle|^2}{\|x\|^2} \leq \|y\|^2$$

Set  $z \triangleq y - \frac{\langle y, x \rangle}{\|x\|^2} x$ . We then have

$$\langle z, x \rangle = \langle y - \frac{\langle y, x \rangle}{\|x\|^2} x, x \rangle = \langle y, x \rangle - \frac{\langle y, x \rangle}{\|x\|^2} \langle x, x \rangle = 0$$

Then from  $y = z + \frac{\langle y, x \rangle}{\|x\|^2} x$ , we can now deduce

$$\begin{aligned} \langle y, y \rangle &= \langle z + \frac{\langle y, x \rangle}{\|x\|^2} x, z + \frac{\langle y, x \rangle}{\|x\|^2} x \rangle \\ &= \langle z, z \rangle + \left| \frac{\langle y, x \rangle}{\langle x, x \rangle} \right|^2 \langle x, x \rangle \\ &= \langle z, z \rangle + \frac{|\langle x, y \rangle|^2}{\langle x, x \rangle} \end{aligned}$$

Because  $\langle z, z \rangle \geq 0$ , we now have

$$\langle y, y \rangle = \langle z, z \rangle + \frac{|\langle x, y \rangle|^2}{\langle x, x \rangle} \geq \frac{|\langle x, y \rangle|^2}{\langle x, x \rangle} \quad (\text{done})$$

The equality hold true if and only if  $\langle z, z \rangle = 0$ . This explains the other two statements regarding the equality. ■

The proof is clearly geometrical. If one wish to remember the proof, one should see the trick we use is exactly

$$z \triangleq y - |y| (\cos \theta) \hat{x} \text{ is the projection of } y \text{ onto } x^\perp$$

Then all we do rest is just expanding  $|y|^2 = |z + \tilde{x}|^2$ , where  $\tilde{x} = y - z = |y| (\cos \theta) \hat{x}$ , which give the answer and is easy to compute since  $z \cdot \tilde{x} = 0$ .

Now, with Cauchy-Schwarz Inequality, we can check the triangle inequality

$$\begin{aligned}
 \|x + y\|^2 &= \langle x + y, x + y \rangle \\
 &= \langle x, x \rangle + \langle x, y \rangle + \langle y, x \rangle + \langle y, y \rangle \\
 &= \langle x, x \rangle + \langle y, y \rangle + 2 \operatorname{Re} \langle x, y \rangle \\
 &\leq \|x\|^2 + \|y\|^2 + 2 |\langle x, y \rangle| \\
 &\leq \|x\|^2 + \|y\|^2 + 2\|x\| \cdot \|y\| = (\|x\| + \|y\|)^2
 \end{aligned}$$

### (Euclidean Space Abstract Part)

By a **concrete Euclidean Space**, we mean some space of  $n$ -tuple  $(x_1, \dots, x_n)$  over  $\mathbb{R}$ , equipped with inner product  $\langle \cdot, \cdot \rangle_E$  defined by

$$\langle (x_1, \dots, x_n), (y_1, \dots, y_n) \rangle_E = \sqrt{\sum_{k=1}^n (y_k - x_k)^2}$$

By an **Euclidean Space**, we simply mean a finite dimensional vector space  $V$  over  $\mathbb{R}$ , equipped with an inner product  $\langle \cdot, \cdot \rangle$  such that there exists a concrete Euclidean space  $E$  and an isomorphism  $\phi : V \rightarrow E$  such that

$$\langle x, y \rangle = \langle \phi(x), \phi(y) \rangle_E \quad (x, y \in V)$$

Note that if you define  $\langle \cdot, \cdot \rangle$  on the space of  $n$ -tuples  $(x_1, \dots, x_n)$  over  $\mathbb{R}$  by

$$\langle (x_1, \dots, x_n), (y_1, \dots, y_n) \rangle = 2 \sqrt{\sum_{k=1}^n (y_k - x_k)^2}$$

Then, the space of  $n$ -tuple is clearly not a concrete Euclidean space, but a Euclidean space.

# Chapter 5

## Beauty

### 5.1 Euler's Formula

Suppose that we define

$$\begin{aligned}\exp(z) &\triangleq \sum_{n=0}^{\infty} \frac{z^n}{n!} & (z \in \mathbb{C}) \\ \sin(z) &\triangleq \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} z^{2n+1} & (z \in \mathbb{C}) \\ \cos(z) &\triangleq \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} & (z \in \mathbb{C})\end{aligned}$$

Some properties we are familiar with is now easily seen using basic technique we learned in Chapter 3.

(a)  $\exp(z), \sin(z), \cos(z)$  are well defined on  $\mathbb{C}$  by Cauchy-Hadamard 3.48.

$$(b) \begin{cases} \exp(x) \\ \sin(x) \\ \cos(x) \end{cases} \in \mathbb{R} \text{ provided } x \in \mathbb{R}.$$

$$(c) \begin{cases} \exp(0) = 1 \\ \sin(0) = 0 \\ \cos(0) = 1 \end{cases}$$

(d)  $\exp(x)$  is strictly increasing on  $\mathbb{R}$  ( $\because |y^n - x^n| \leq |y^n| + |x^n|$ )

- (e)  $\exp(x) \nearrow \infty$  as  $x \rightarrow \infty$  ( $x \in \mathbb{R}$ )
- (f)  $\exp(x) \cdot \exp(y) = \exp(x + y)$  ( $x \in \mathbb{C}$ ) by Merten's Theorem of Cauchy Product 3.9.16
- (g)  $\exp(x) \searrow 0$  as  $x \rightarrow -\infty$  ( $x \in \mathbb{R}$ )
- (h)  $\begin{cases} \frac{d}{dz} \exp(z) = \exp(z) \\ \frac{d}{dz} \sin(z) = \cos(z) \\ \frac{d}{dz} \cos(z) = -\sin(z) \end{cases}$  ( $z \in \mathbb{C}$ ), using Term-by-Term Differentiation 3.10.1.
- (i)  $\exp(x)$  is convex on  $\mathbb{R}$  ( $\because (e^x)'' = e^x > 0$ )
- (j)  $\exp(nz) = (\exp(z))^n$  ( $z \in \mathbb{C}, n \in \mathbb{Z}$ ), by induction and Merten's Theorem of Cauchy Product 3.9.16.

In particular, we have **Euler's Formula**.

**Theorem 5.1.1. (Euler's Formula)**

$$\exp(iz) = \cos(z) + i \sin(z) \quad (z \in \mathbb{C})$$

*Proof.* Define

$$I_i(n) \triangleq \begin{cases} 1 & \text{if } n \equiv 0 \pmod{4} \\ i & \text{if } n \equiv 1 \pmod{4} \\ -1 & \text{if } n \equiv 2 \pmod{4} \\ -i & \text{if } n \equiv 3 \pmod{4} \end{cases}$$

Compute

$$\begin{aligned} \exp(iz) &= \sum_{n=0}^{\infty} \frac{(iz)^n}{n!} \\ &= \sum_{n=0}^{\infty} \frac{I_i(n) z^n}{n!} \\ &= \sum_{n=0}^{\infty} \frac{I_i(2n)}{(2n)!} z^{2n} + \frac{I_i(2n+1)}{(2n+1)!} z^{2n+1} \quad (\because \text{this is a sub-sequence of (5.1)}) \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} + i \cdot \frac{(-1)^n}{(2n+1)!} z^{2n+1} \end{aligned} \tag{5.1}$$

Now, we can conclude

$$\begin{aligned}\cos(z) + i \sin(z) &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} + i \cdot \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} z^{2n+1} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} + \sum_{n=0}^{\infty} i \cdot \frac{(-1)^n}{(2n+1)!} z^{2n+1} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} + i \cdot \frac{(-1)^n}{(2n+1)!} z^{2n+1} = \exp(iz)\end{aligned}$$

■

## 5.2 Alternative Definitions of $e^x$

**Theorem 5.2.1. (First Characterization)** for all  $x \in \mathbb{R}$ , the sequence  $\{(1 + \frac{x}{n})^n\}_{n \in \mathbb{N}}$  has limit

$$\lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n = \sum_{k=0}^{\infty} \frac{x^k}{k!}$$

*Proof.* The proof is trivial if  $x = 0$ . First suppose  $x \in \mathbb{R}^+$ . Set

$$t_n \triangleq \left(1 + \frac{x}{n}\right)^n \text{ and } s_n \triangleq \sum_{k=0}^n \frac{x^k}{k!}$$

We wish to show

$$\limsup_{n \rightarrow \infty} t_n \leq \lim_{n \rightarrow \infty} s_n \leq \liminf_{n \rightarrow \infty} t_n$$

We first prove

$$\limsup_{n \rightarrow \infty} t_n \leq \lim_{n \rightarrow \infty} s_n$$

Use Binomial Theorem to compute

$$\begin{aligned} t_n &= \left(1 + \frac{x}{n}\right)^n = \sum_{k=0}^n \binom{n}{k} \left(\frac{x}{n}\right)^k \\ &= \sum_{k=0}^n \frac{x^k}{k!} \cdot \frac{n(n-1) \cdots (n-k+1)}{n^k} \leq \sum_{k=0}^n \frac{x^k}{k!} = s_n \text{ (done)} \end{aligned}$$

We now prove

$$\lim_{n \rightarrow \infty} s_n \leq \liminf_{n \rightarrow \infty} t_n$$

Fix  $\epsilon$ . Because  $s_n \nearrow$ , we know there exists  $m$  such that

$$s_m > \lim_{n \rightarrow \infty} s_n - \epsilon$$

Fix such  $m$ . Observe

$$t_n = \sum_{k=0}^n \binom{n}{k} \left(\frac{x}{n}\right)^k \geq \sum_{k=0}^m \frac{x^k}{k!} \cdot \frac{n(n-1) \cdots (n-k+1)}{n^k} \quad (n \geq m)$$

Clearly, there exists  $N$  such that

$$\forall n > N, \left| \left( \sum_{k=0}^m \frac{x^k}{k!} \cdot \frac{n(n-1) \cdots (n-k+1)}{n^k} \right) - s_m \right| \leq s_m - \left( \lim_{n \rightarrow \infty} s_n - \epsilon \right)$$

Then, we see for all  $n > \max\{N, m\}$

$$\begin{aligned} t_n &\geq \sum_{k=0}^m \frac{x^k}{k!} \cdot \frac{n(n-1) \cdots (n-k+1)}{n^k} \geq s_m - (s_m - \lim_{n \rightarrow \infty} s_n - \epsilon) \\ &= \lim_{n \rightarrow \infty} s_n - \epsilon \text{ (done) (done)} \end{aligned}$$

For negative real, we only wish to show

$$\sum_{n=0}^{\infty} \frac{(-x)^n}{n!} = \left( \sum_{n=0}^{\infty} \frac{x^n}{n!} \right)^{-1} \text{ and } \lim_{n \rightarrow \infty} \left( 1 - \frac{x}{n} \right)^n = \left( \lim_{n \rightarrow \infty} \left( 1 + \frac{x}{n} \right)^n \right)^{-1}$$

Because the convergence is absolute, we can use Merten's Theorem for Cauchy product (Theorem 3.9.16) to compute

$$\begin{aligned} \left( \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} \right) \cdot \left( \sum_{n=0}^{\infty} \frac{x^n}{n!} \right) &= \sum_{n=0}^{\infty} \left( \sum_{k=0}^n \binom{n}{k} (-1)^{n-k} \right) \frac{x^n}{n!} \\ &= \sum_{n=0}^{\infty} (1-1)^n \frac{x^n}{n!} = 1 \text{ (done)} \end{aligned}$$

We first prove

$$\lim_{n \rightarrow \infty} \left( 1 - \frac{x^2}{n^2} \right)^n = 1$$

Computing term by term, it is clear that

$$\limsup_{n \rightarrow \infty} \left( 1 - \frac{x^2}{n^2} \right)^n \leq 1$$

Using Bernoulli's Inequality (Theorem 3.5.1), we see that for large enough  $n$ , we have

$$\left( 1 - \frac{x^2}{n^2} \right)^n \geq 1 - \frac{x^2}{n}$$

This then implies

$$\liminf_{n \rightarrow \infty} \left( 1 - \frac{x^2}{n^2} \right)^n \geq 1 \text{ (done)}$$

Compute

$$\begin{aligned}\lim_{n \rightarrow \infty} \left(1 - \frac{x}{n}\right)^n &= \lim_{n \rightarrow \infty} \left(\frac{1 - \frac{x^2}{n^2}}{1 + \frac{x}{n}}\right)^n \\ &= \frac{\lim_{n \rightarrow \infty} (1 - \frac{x^2}{n^2})^n}{\lim_{n \rightarrow \infty} (1 + \frac{x}{n})^n} = \frac{1}{\lim_{n \rightarrow \infty} (1 + \frac{x}{n})^n} \quad (\text{done})\end{aligned}$$

■

$$\ln(x) \triangleq \int_1^x \frac{1}{t} dt$$

By FTC (Theorem 3.7.1), it is easy to see that

$$\frac{d}{dx} \ln(x) = \frac{1}{x} \quad (x \in \mathbb{R}^+)$$

To see

$$\ln(xy) = \ln(x) + \ln(y)$$

Fix  $y \in \mathbb{R}^+$  and set

$$f(x) \triangleq \ln(x) \text{ and } g(x) \triangleq \ln(xy)$$

Conclude  $f'(x) = g'(x)$ , and use FTC (Theorem 3.7.2) to conclude  $f - g$  is some fixed constant  $k$ . Now, see that

$$g(1) = f(1) + k \implies k = \ln(y)$$

Then, we have

$$\ln(xy) = g(x) = f(x) + k = \ln(x) + \ln(y)$$

Using induction, it is now easy to see

$$\ln(x^n) = n \ln(x) \quad (n \in \mathbb{Z}_0^+)$$
